sively, reveal their true affinities. Now we have seen that the whole of the internal structure in the herbivorous Cetacea differs as widely from that of the carnivorous Cetacea as do their habits; that the amount of variation is as great as well could be in animals of the same class existing in the same great deep. The junction of the Dugongs and Manatees with the true Whales cannot therefore be admitted in a distribution of animals according to their organization. With much superficial resemblance, they have little real or organic resemblance to the Walrus, which exhibits an extreme modification of the amphibious carnivorous type. I conclude therefore that the Dugong and its congeners must either form a group apart, or be joined, as in the classification of M. de Blainville, with the Pachyderms, with which the herbivorous Cetacea have the nearest affinities, and to which they seem to have been more immediately linked by the now lost genus Dinotherium.

These Aquatic Pachyderms consist of three genera: namely, the Manatees (Manatus, Cuv.); the Dugongs, Histoires, Ill. (Dugongus, Camper, &c.); and the Mammals (Stellerus, Cuv., Hyotis, Ill.).

Manatus.

Generic Character.—Body oblong; molar teeth marked with two transversal elevations; crown with no canines in the adult; vestiges of nail on the edges of their anterior extremities or pectoral fins; pectoral mammae; skin very thick and naked; whiskers very strong and close set; horizontal tail thick, tegumentary, and elongated oval.

Dental formula:—Incisors, 3-3; molars, 4-4 = 34.

Cuvier describes the Manatees as having an oblong body terminated by an elongated oval fin; eight molar teeth in each jaw, with a square crown marked by two transverse ridges; neither incisors nor canines in the adult; but in the very young ones two small pointed teeth are found in the intermaxillary bones, which disappear early. The vestiges of nails are observable on the edges of their flippers, which they use dexterously enough in creeping and carrying their young. This has caused these organs to be useless to hands, whence their name Manati, or Ma-

Geographical Distribution of the Genus.—The warmer parts of America and its islands: Western Africa.

The mummies of the Manatees and Dugongs are pectoral, and this conformation, joined to the adroit use of their flippers (whose five fingers can be easily distinguished through the investing membranes, four of them being terminated by nails) in progression, nursing their young, &c., have caused them, when seen at a distance with the anterior part of their body out of the water, to be taken for some creature approaching to human shape so nearly (especially as their muzzle is thick set with hairs, giving somewhat of the effect of human hair or a beard), that there can be little doubt that a few of the tales of Mer-
man and Mermaids have had their origin with these animals, as well as with Seals and Walruses. Thus the Portuguese and Spaniards give the Manatee a denomination which signifies Woman-fish; and the Dutch call the Dugong, Baardmanetje, or Little Bearded Man. A very little imagination, and a memory for only the marvellous portion of the appearance sufficed, doubtless, to complete the metamorphosis of this half woman or man, half-fish, into a Siren, a Mermaid, or a Merman, and the wild recital of the voyager was treasured up by such writers as Mallet, Laepke, Dapper, Bois, Sachs, Velasquez, and others, who, as Cuvier well observes, have displayed more learning than judgment.

Example, Manatus americanus. Description.—The American Manatee is of rounded form, and can be filled only with a leathern bottle or wine skin. The head is conical, and no depression marks its junction with the body; the muzzle is stout and fleshy, semicircular at its upper part, where are the two semilunar apertures of the nostrils. There is no tail, and two tufts of stiff bristles spring from its sides: the lower lip is shorter and straighter than the upper, and the internal lining of both consists of short hard very thick hairs. The mouth is not large, and the eyes are small. Two small fissures in the skin form the only appearance of external ears. The flippers or swimming paws have more freedom of motion than those of the true Whales; the articulations of the fingers may be felt through the skin, and are endowed with considerable power and motion. There is no nail on the thumb, but the four fingers are furnished with nails, that of the little finger being very small. The skin is greyish and coarse, like bull’s hide, some say slightly shagreened, and having isolated hairs scattered here and there; these hairs are most numerous at the angle of the mouth and behind the paws. The mannae are situated on the breast, and are not much developed, except during the period when they are called into action for the supply of the young.

This species reaches twenty feet in length, and is the Sirena, and Fauche Marine, and Femme Marine, of the French: Sea-Cow of the English. Strange figures were given of it by the older naturalists; that in Hernandez has the fore-feet terminated with solid hoofs.

Geographical Distribution. — Manatees are found on the rivers and the Antilles, about the mouths of rivers.

Habits, Food, &c. — The Manatees are gregarious, and generally go in troops. The young are usually placed in the centre of the herd for protection, and on the approach of danger, all unite for that common safety. It is alleged that, when one has been struck by a harpoon, its companions will tear out the weapon; and so are attached to their young that if the calf be taken the captors are sure of the mother, from the recklessness with which her maternal affection leads her to the place of capture. If the mother be captured, the young follow her to the shore and fall an easy prey.

The shallow bays of the Antilles and the quiet creeks of the South American rivers, particularly in Guiana and the Brazil, are the favourite haunts of the Manatee. They were formerly abundant at the mouths of the Orinoco and Amazon, ascending many miles, even into their tributaries and the fresh water lakes. There their actions are recorded as being similar in some respects to the whales, such as breaching or leaping to a considerable height out of the water. The food is entirely vegetable, consisting of submerged plants and littoral herbs, principally. According to Hernandez, Humano more coy, forina supina in littere fere tota proeminente, accelerate quadam superficiem manus rectas, that only one young is produced at a birth. The milk is said to be agreeable to the taste.

Utility to Man. — The mild inoffensive manners of the Manatee, and the unsuspecting nature of the animal, make it an easy prey to the hunter, who pursues it for the sake of the flesh, which all pronounce to be excellent, both fresh and salted. Hernandez compares it to well fattened pork of pleasant flavour, but says that it is noxious to those labouring under lues venereum. Others compare it, when boiling, to best of veal in flavour, and state that when salted it makes excellent sea provision.

It is alleged that formerly they were so plentiful within ten or twelve leagues of Cayenne, that a large boat might be filled with them in a single day, when their flesh was sold in the market at about threepence a pound. But the eagerness with which it was purchased soon reduced the numbers, and made them comparatively scarce.

The capture is generally effected by means of the harpoon. At St. Domingo the hunters approached them in a small boat, and struck them with a large harpoon to which a long stout cord was made fast. The struck animal made violent efforts to escape, carrying with it the harpoon and cord, to the end of which a cork or piece of light wood served as a buoy was attached, and indicated the whereabouts of the manatee. After a while the hunters took hold of the rope and at last drew the exhausted animal on shore, where it was killed. The sport of manatee-eating, thus conducted, is described as highly diverting, but the boat is sometimes upset by the struggles of the animal in the shoals.

Manatees have reached Europe. The carcass of one which had been long dead, is recorded to have come on shore at Newhaven in the Frith of Forth, in the autumn of 1765; and Duhamel states that one with its cub was thrown on shore near Dieppe.

Teeth of Dugong. (P. Ovo.)

The attention of Professor Owen was particularly directed to the dentition of the Dugongs of different sexes which he examined, from which it appeared that, as in the Narwhal, the permanent teeth of the female are arrested in their growth, and remain throughout life concealed within the substance of the intermaxillary bones and the alveolar incumbrance. The

VOL. XXVII. — 2 H

Digitized by Google
cavity of the tusks, he states, is in like manner filled up by the secretion of the pulp which retrogrades in the course of its absorption, and hence the tusks are solid, like the corresponding tusks in the female Narwhal, or at least, present only a shallow cavity at their expanded and distorted base. He found in one cranium of a male Dugong, in the upper jaw, the deciduous incisors or tusks co-existing with the permanent ones. In the skull of a male, which had 3-3 molars, the sockets of the deciduous incisors were obliterated, and the points of the permanent ones projected from their sockets. Not more than twenty pairs of teeth on each side of the jaw, appear to be developed in this animal.

"It is obvious," says Professor Owen, "that the different form and condition of the tusks thus observed in the heads of Dugongs of the same size and age, might be regarded as indicating the necessity on the anterior edge of the tusks of forming the short and nearly vertical snout, was furnished with soft papillae and a few bristles; a horny substance covers the lips, the upper of which is movable and tumid on the edge; the lower is much smaller, resembling a round or oblong chin. The inside of the cheeks is furnished with strong projecting bristles. The nostrils are situated on the summit of the upper jaw, where it curves downwards, and penetrate obliquely, so that the upper surfaces are placed upon the lower surface of the mouth, a valve capable of being shut at the will of the animal. The eyes are small. The little aperture of the ear is hardly perceptible. The mammae are placed on the chest, beneath the thick and fleshy flippers or paws, which are rather oval than circular, and there is no noticeable appearance of nails. The tail is broad, and lobated or crescent-shaped. The skin is three-quarters of an inch thick, of a uniform blueish colour, sometimes blotted with white below. Length from seven to eight feet.

Geographical distribution. Sumatra and all the warm seas of the Indian archipelago. It is said to have been observed at the north of New Holland, and to have once been common at the island of Rodriguez.

Habits. Food, &c. The external form of the Dugong, says Professor Owen, is not a very beautiful adapted for swimming rapidly through the water as that of the dolphin and other carnivorous cetacea, which subsist by a perpetual pursuit of living animals. In these the snout is conical and peculiarly elongated, and in some, as the Delphinus Gangeticus, the jaws are provided with an external difference so great as to give them every advantage in seizing their swift and slippery prey; whilst in the herbivorous Dugong the snout is as remarkable for its obtuse truncate character—a form however which is equally advantageous to it, and well adapted to its habits of browsing upon the algae and fauces which grow upon the submarine rocks of the Indian seas. As, from the fixed nature of the Dugong’s food, the motions of the animal during the time of feeding must relate more particularly to the necessity of breathing to enable it to respire, its tail, the principal locomotive organ of ascent and descent, is proportionally greater than in the true cetacea, its breadth being rather more than one-third the length of the whole body. But the most important external differences are seen in the presence of the membrana nictitans, in the anterior position of the nostrils, and in the situation of the mammary, which are pectoral, or rather axillary, being situated just behind the roots of the flippers; in the female specimens examined their base was about the size of a shilling, and they projected about half an inch from the surface. A considerable ridge extends along the middle of the upper surface of the posterior part of the back, which is continued upon and terminates in the tail.

The haunts of the Dugong, which does not appear ever to frequent the land or fresh-water, are generally in the sea-shallows, where the water is not more than two or three fathoms.

Sir Stamford Raffles states that during six months four of these animals were secured at Singapore, but that the greatest number is said to be found in the southern monsoon, when the sea is most calm, near the mouth of the Johore River. They are usually caught by spearfishing, in which the natives are very expert, during the night, when the animals indicate their approach by a snuffling noise which they make at the surface of the water. The first object of the captor is to secure and elevate the tail, when the animal becomes perfectly powerless. Sir Stamford adds, that the Dugongs are seldom caught at Singapore above eight or nine feet in length; but how much larger they grow is not ascertained, as, when they exceed that size, their superior strength enables them to make their escape.

Leguat, who speaks of them as occurring at the Isle of Pines, says they might be considered the largest of all the crab-eating mammals. It is not long since, he says, that they were twenty feet long, but were very easily taken. They fed in flocks like sheep in three or four fathoms’ water, and made no attempt at escape when approached. Sometimes they were shot at the end of the musket, sometimes laid hold of and forced on shore. Three or four hundred were met with together, and they were so far from shy that they suffered themselves to be handled, and the fattest were thus selected. The larger ones were avoided, not only on account of the trouble they occasioned, but because the meat was not so good as that of the smaller and younger ones.

The female Dugong produces generally only one young at a birth, and to this the mother bears such strong affection that, if the young is speared, the mother will not depart, but she may be taken at the behest of the Malaya. She is so affectionate that she will take the place of her child and they are so near from shyness that they suffer themselves to be handled, and the fattest were thus selected. The larger ones were avoided, not only on account of the trouble they occasioned, but because the meat was not so good as that of the smaller and younger ones.

The female Dugong produces generally only one young at a birth, and to this the mother bears such strong affection that, if the young is speared, the mother will not depart, but she may be taken at the behest of the Malaya. She is so affectionate that she will take the place of her child and they are so near from shyness that they suffer themselves to be handled, and the fattest were thus selected. The larger ones were avoided, not only on account of the trouble they occasioned, but because the meat was not so good as that of the smaller and younger ones.

Utility to Man. The flesh is delicate, and is said to be superior to that of the humpback or common ox. The Dugong is sometimes said to be the most common animal in the Gulf of Paria, and the king has a right to all that are taken. Sir Stamford Raffles states that this species afforded much satisfaction on the table, as the flesh proved to be most excellent beef.

The Dugong of the Red Sea is considered different from that above noticed, by Professor Rüppell, who describes it by the name of Halicore parthenica, under the impression that it was with the skin of this species that the Jews were directed to veil the Tabernacle. He saw it swimming among the rocks of the islands on the Abyssinian coast near the Dakhla islands. The fishermen harnessed a female, which he dissected, ten feet long. The Arabs stated that they live in pairs or small families, that they have feeble voices, feed on algae, and that in February and March bloody battles occur in which the males participate, and the females do not become pregnant until the eighteenth year. The females are born in November and December. The flesh, teeth, and skin are esteemed by the Arabs.

The Dugong.

For an account of the northern form of this group, Str.-lers or Bythina, our limits compel us to refer the reader to Steller’s description in the second volume of the New...
Memoirs of the Petersburg Academy' (1751). Very little
addition has since been made to its history.

*Zoophagous Cetacea.*

Delphinus.

These have an elongated body, with their jaws more or
less projecting in the form of a beak, are without tusks,
but most frequently furnished with a great number of
Teeth simple and equal in size, which are however wanting
sometimes in some species; no baleen or whalebone;
blow-holes with a common opening in a crescent shape
on the head.

The dental formula of the family may be stated gene-
rrally as consisting of from 84 to 95 teeth in the upper jaw,
and from 65 to 75 in the lower jaw (190. 10 to 190).

Space will not permit us to notice more than two of the
numerous genera of this family.

*Phocoena.*

Generic Character.—Muzzle short, convex, and not
terminated in a rostrum; teeth numerous, placed irregularly
in each jaw; a dorsal fin.

Dental formula:—Molars, 40 to 46; incisors, 40 to 40 = 80 to 92.

Teeth of Porpoise. (F. Cuv.)

Example, *Phocoena communis,* Delphinus phocaena,
Linn.

Description. Upper part of the body deep bluish or
greenish black fading on the sides into the polished silvery
whiteness of the belly. The brownish flippers rise from a
white ground. Length from four to five feet.

Geographical Distribution.—Atlantic Ocean. Seas of
Europe.

This appears to be the *phocoena* (phocaena) of Aristot.
('Hist. Anim.' vi., 12). Some, Pennant and others, have
supposed it to be the *Tursio* of Pliny ('Nat. Hist.,' ix., 9),
which, according to the Roman naturalist, bears some
likeness to the Dolphins, of which he relates so many
aneedotes illustrative of their affection for man in the pre-
ceding chapter. It is the *Porpo sece* of the Italians
(whence probably the English name Porpoise), *Marronin*
of the French; *Morschein* and *Tumble* of the Swedes;
*Morschwein* of the Germans; and *Lamhiydja* of the
antient British.

Habits, Food, &c.—Porpoises swim in shoals, and drive
the mackerel, herrings, and salmon before them, pursuing
them up the bays 'with the same eagerness,' says Pennant,
'as a pack of dogs does a hare.' In some places they almost
darken the sea as they rise above water to take breath;
they not only seek for prey near the surface, but often de-
send to the bottom in search of sand-eels and sea-worms,
which they root up out of the sand with their noses in the same
manner as the hogs do in the field for their food. In fine
weather they leap, roll, and tumble in the manner so well
known, principally in the spring and summer, which is sup-
posed to be their rutting season. They go up the rivers in
pursuit of the salmon, to which they are a deadly enemy,
and other fish; and have been seen high in the Loire,
Charente, and Seine in France. It has been remarked that
when the porpoises are gamboling in the spring and sum-
mer, they appear heedless and blind to all danger and risk,
which, as their brain is highly developed, strengthens the
supposition that they are, at such times, actuated by the
sexual impulse to an extent that lessens their usual warie-
ness. On the 23rd May, 1842, we saw, about 10 A.M.,
two rolling and sporting a little above London Bridge
towards the Surrey shore. They seemed to disregard the
numerous steam-vessels which were constantly passing, and
to pay no attention to the wherries, some of which went
close to them. The man on the look-out in the steamer
from whose deck we watched them said that they had been
seen between five and six that morning near Southwark
Bridge, and that one of them had been hooked with a boat-
hook, but had got away. It was blowing fresh from the
south-west, and the tide was running up; the time for high
water at London Bridge that day being 6 P.M.

The period of intercretion is said to be six months,
and the young at the birth twenty inches in length. The
mother watches over it with the most tender care.

Those who have seen the porpoise in pursuit of the
salmon, describe the scene as most interesting from the
efforts of the salmon to escape, and the admirable
manner in which the porpoise counteracts their attempts. In
their distress the salmon frequently spring high out of the
water, but their ever watchful foe hides their release, and by
its quick, and well directed turns, seldom fails to
secure its prey.

*Utility to Man.*—The oil produced from the fat sur-
rounding the body is of the purest kind, and the skin when
carefully tanned and dressed is used for wearing-apparel,
and for coverings for carriages. The skins of porpoises
on the west coast of Ireland are said to be immense, and might
be well worth the attention of the neighbouring population if
furnished with boats and proper implements for their
capture, and conversion to economic purposes. An article
in a London newspaper, the flesh of the porpoise is stated
to be of more value than that of any other animal.

Received for dressing it appear in the 'Forme of Curte,' compiled (cir.
1390) by the master cooks of King Richard II. It appears to have
been used in France, as before mentioned, in broth, and roasted, and was
evidently used both fresh and salted. Several of them were on
the board at the great feast held at the 'intronization' of
George Nevell, Archbishop of York, in the reign of Edward
IV. In Henry VIII.'s time it continued to be a royal dish,
and was in fashion in the reign of Elizabeth. It appears to
have been, in those days, generally presented as a roast with a
sauce made of fine white bread crumbs, mixed with vine-
gar and sugar. The common dolphin, *Delphinus delphis,*
was then considered so great a delicacy, that, according to
Dr. Caius, one which was taken in his day was thought a
present worthy of the Duke of Norfolk, who distributed it
amongst his friends: it was roasted and dressed with the
porpoise-sauce last above mentioned. At a later period,
the porpoise kept its ground on the table of Roman Catho-
lics for fish-days and during Lent. Nor have modern nav-
igators found it undesirable food. Captain Colnett's people,
who fell in with numbers of them off the Mexican coast,
mixed their flesh with their salt-pork—making excellent
sausages, which formed their ordinary food. Captain Basil
Hall speaks with some relish of a dish of porpoise-cut-
lets, well separated from the investing land and blubber,
which was served at his table with such happy effect that
the dish left his cabin empty.

The flesh of the porpoise is the Greenlander's great
dainty, and he quails its oil as the most delicious of
draughts.

*Delphinus*

Generic Character.—Head obtuse, muzzle short and co-
obial, or terminated in an elongated rostrum; number of
teeth variable; no dorsal fin.

Dental formula, according to F. Cuv., 9 - 9 = 34.

8 - 8.
Example, Delphinapterus leucas, Delphinus leucas, Gm.
Description.—Head obtuse, muzzle short and conical; a small angular finness is to be the dorsal fin; colour, yellowish white or cream-colour; but they have been seen yellowish approaching to orange, and white tinged with red. The young with brownish spots, and occasionally, blue or slaty. No external ear, mouth small, eye hardly larger than that of man; iris blue. Spirecle on the vertex with its horns turned backwards. Length from 12 to 18 feet.

Geographical Distribution.—The Northern Ocean. This is the Beluga and White Whale of authors and navigators. White Flook of the whalemen.
One of these dolphins haunted the Frith of Forth in the summer of 1815 for nearly three months, passing almost daily upwards, and again retiring, with the flood and ebb. It was supposed to be in pursuit of salmon, and, after many unsuccessful attempts, to have swallowed one; the salmon was killed immediately, and the fire-arms and spears. Mr. Bald, of Alloa, bought it and sent it to Professor Jamieson: it is now in the Edinburgh Museum, and formed the subject of the interesting observations of Dr. Barclay and Mr. Neil in the Transactions of the Wernherian Society.
Mr. Neil remarks that the shape of this animal is very symmetrical, suggesting the idea of perfect adaptation to rapid progression in the water. Its head, he observes, is small and long-headed, and over the forehead there is a round cushion of flesh and fat: the body continues to swell as far as the large, thick, oval flippers, and from that point gradually diminishes to the setting on of the tail, which is powerful, and described as bent under the body in swimming, and propelling the animal with the velocity of an arrow.
The contradictory accounts of the number of the teeth arise probably from differences of age. In the specimen examined by Mr. Neil, they were 9 to 0.
Habits, Food, &c.—The higher and Arctic latitudes appear to be the chosen haunts of the Beluga. They abound in Hudson’s Bay, Davis’s Straits, and on parts of the southern coasts of Asia and America, where they ascend the large rivers. Steller noticed them at Kamuchka; and in Charles’s time they were numerous in the Gulf of St. Lawrence, going with the tide as high as Quebec. Disco Island in Greenland is said to abound with them, nor are they scarce at Spitsbergen. Scoresby did not see them lower than Jan Mayen’s Land; he seldom observed them among the ice, but where the water was clear and smoothest. They are described as not at all shy, but often following the ships, tumbling about the boats in herds of forty or fifty, bespangling the surface with their brilliant white and yellowish whiskers. The whale-fisher seldom disturbs these beautiful creatures, for they are not only difficult to strike of account of their activity, but, when stricken, the harpoon frequently drawer, and if it holds, the capture is but of little value. Sir Charles Gieseeck speaks of their regular annual visitation at November. The whales of Greenland, where they become a seasonable supply to the natives when other provisions fall short. They arrive in herds with stormy weather and south-west winds, and are taken with harpoons and strong nets. Cod, haddock, flounders, &c., are said to be the usual food of the Beluga.

Utility to Man.—The oil is reported to be of the best, whitest, and finest quality, and of their skins a sort of Mo-

rocco leather is said to be made, which, though thin, will resist a musket-ball. The internal membranes are used for windows, and bed-surfains, and the sinews for thread. The flesh, it is asserted, resembles beef, though somewhat oily. Hans Egede describes both it and the fat as having no bad taste; when it is marinated with vinegar and salt, and says that it is then as well flavoured as any pork whatever. He declares the lips also and the tail ‘pecked or sauced’ be very good eating, so that, according to Hans, he is very good cheer.’

Monodon.

Generic Character.—Body elongated, a slight longitudinal projection or crest in place of the dorsal fin; flippers oval.
Dental formula: 1—1; molars 0.

Example, Monodon monoceros.
Description.—General form long ovoid. Head about a seventh of the whole length, with a slight depression behind it where it joins the body; forehead rising suddenly and almost perpendicularly from the mouth, then depth; but the belly was everywhere with a hair glittering in a slight elevation. Blow-hole directly over the eye, which is small, the orbit oval, the iris chestnut, and the selerotic coat white. The back rises gradually to a few inches behind the flippers, where it is thickest. There are four teeth, the upper incisors and upper parts on each side, giving the body, especially towards the tail, somewhat of a squared appearance. Flippers elliptical and rather curved, the anterior edge thickest, and small in proportion to the size of the animal. The tail, about two inches high and between two and three feet long, about midway between snout and tail, in place of a dorsal fin. Tail in the proportion of about twenty inches in length to four feet in breadth. Colour blackish-grey on the back, variegated with numerous dark spots running into each other, forming a dusky-black surface; the sides with paler and more open spots of grey on a white ground. No spots on the belly. The ground colour in old narwhals is stated to be entirely white, with the edge of the head variegated, as in a normal man; the old male narwhals have the upper incisors incised, but the lower perfectly smooth; whilst on the belly they are faint and few, occurring at intervals, and considerable spaces being spotless. In one stranded on the Elbe the skin was white as snow, marked with a multitude of dark spots to a considerable depth; but the belly was everywhere with a hair glittering. Length from fifteen to sixteen feet without the tusks.

Geographical Distribution.—The Northern Ocean. This is the Narwhal of the Germans; Narwal, Unicorn, and Livorne de Mer of the French; and Narwhal and Lunevr Whale of the Dutch. The Narwhal, Monodon monoceros, is a species of whale which is distinguished by the long, curled, and spirally twisted tusk, or narwhal’s tusk, that is frequently carried by the male of the species. The Narwhal is a toothed whale, and like all other toothed whales, it is characterized by the presence of teeth, which are modified to form tusks. The Narwhal’s tusk is a single, spirally twisted, hair-like structure that is shed and replaced throughout the life of the animal. The Narwhal is most commonly found in the cold Arctic waters of the Northern Hemisphere, particularly in the Bering Sea, the Chukchi Sea, and the Davis Strait. It is a rare and elusive animal, and their tusks are highly valued as decorative items.
nearly three times as great as the width of its own mouth. As the animal in which these remains were found had a
tusk of seven feet, Mr. Scoresby apprehended that this
instrument had been employed in the capture of the
fishes on which it had fed. It seemed probable
to him that the skates had been pierced with the horn and
killed before they were devoured; otherwise, he observes,
it is difficult to imagine how the narwhal could have swal-
lowed them, or how a fish of any activity would have per-
mitted itself to be taken, and sucked down the throat of
that smooth-mouthed animal without teeth to detach and com-
press it.

The Narwhals swim with great swiftness. When at the sur-
face for respiration, they blow repeatedly with considerable
force, and then frequently lie motionless for several minutes
with their back and head just above water. Mr. Scoresby
describes them as often sitting about his ship, sometimes
in bands of fifteen or twenty together, often elevating
their long tusks and crossing them with each other as if
they were fencing. They often uttered a very unusual
sound, resembling the gurgling of water in the throat, which
Mr. Scoresby thinks produced it, as it only occurred when
they reared their tusks, with the front of the head and
mouth out of the water. Several of them followed the
ship, seeming to be attracted by curiosity: as the water was
perfectly transparent, they could be seen descending to the
beel and playing about the rudder for a considerable time.

Sir Joseph Banks stated to Dr. Fleming, who has published
the Wernerian Transactions that a narwhal stranded on the Lincolnshire coast was
found with the whole of its body buried in the mud of the
beach, and seemed safely and securely waiting the return
of the tide.

Utility to Man.—The blubber yields a very superior oil,
which, as well as the flesh, is considered a dainty by the
Greenlander, who regards the Narwhal as the herald of the
Mysticete, in whose neighbourhood the former is, they say,
generally to be found, perhaps from partaking of the same
food. When harpooned, it swiftly dives to about two hun-
dred fathoms, and on its return to the surface is killed by
fences. The Greenlander drives them to fissures in the
sea, where they come up to respire, and kills them with
harpoons, &c. The ivory of the tusk is considered superior to
that of the elephant, it is very dense and hard, very
white, is not subject to become yellow, and is susceptible
of a high polish. They formerly brought a high price, and
many virtues were attributed to them [UNICORN]: they
still form a valued article in commerce. The celebrated
thrones of the Danish kings is stated to be made of the
tusks of this animal.

The Narwhal.

Physeteridae.

Physeter.

Generic Character.—Length of the head equal to a
third or half of the total length; upper jaw large, elevated,
as either without teeth or furnished with very few, which
are short, and nearly entirely hidden by the gum; lower
jaw narrow, and armed with stout conical teeth; orifrices
of the blow-holes united; and situated at the end of the
upper part of the muzzle; no dorsal fin.

This form is described by M. F. Cuvier, who gives it
from the skeleton in the Paris museum, and is confined to
the lower jaw only, from which it may be inferred that in
the French specimen there is no appearance of teeth in the
upper jaw; in the lower there are 27 on each side
*51.

Teeth of Narwhale.

Example, Physeter macrocephalus.

Description.—To render the following abridgment of
the description by Mr. Beale (who, in his excellent work
on the 'Natural History of the Sperm Whale,' has done
more to elucidate this habitat and form than any other
writer) more intelligible, we prefix, as he himself does, his
cut, which is by far the most accurate published figure
extant of the Spermacei Whale.

The head presents a very thick blunt extremity, consti-
tuting about a third of the whole length of the animal;
at its junction with the body is a large protuberance on
the back called 'the bunch of the neck'; immediately
behind this is the thickest part of the body, which from
thence gradually tapers off to the tail, but it does not be-
come much smaller for about another third of the whole
length, when the 'small' or tail commences; and at this
point also, on the back, is a large pyramidal prominence
called 'the hump,' from which a series of smaller processes
run half way down the 'small' or tail, constituting what
the whalers term the 'ridge.' The body then contracts so
much as to become finally not thicker than that of a man,
and terminates by expanding on the sides into the 'fleeks'
or tail, forming a large triangular horizontal fin with a
slight notch or depression posteriorly between the fleeks,
which are about six or eight feet in length, and from
twelve to fourteen in breadth, the largest males or 'Bulls.'
The chest and belly are narrower than the broadest part
of the back, and taper off evenly towards the tail: the
depth of the head and body is, in all parts except the tail,
greater than the width. The head, viewed in front, pre-
sents a broad somewhat flattened surface, rounded and
contracted above, considerably expanded on the sides, and
gradually contracted below, resembling in some degree the
cutwater of a ship. The slit of the single blowing-
hole or nostril is about twelve inches in length. In the
right side of the nose is the 'case,' a cavity for the pur-
pose of secreting and containing an oily fluid, which after
death concretion into a granulated yellowish substance:
this is the spermaceti. In the case of a large whale there
is not unfrequently a ton, or more than ten barrels, of sper-
maceti. Beneath the case and nostril is the elastic 'junk,'
formed of dense cellular tissue strengthened by strong ten-
dinous fibres, and infiltrated with very fine sperm oil and
spermaceti. The mouth extends nearly the whole length
of the head. Both the jaws, especially the lower, are con-
tracted in front to a very narrow point; and when the
mouth is closed the lower jaw is received within a sort of
cartilaginous lip, or projection of the upper one; but
principally in front, for further back at the sides, and
towards the angle of the mouth, both jaws are furnis-
shed
with tolerably well-developed lips. The tongue is small and white. The throat is capacious enough to give passage to the body of a man, presenting a strong contrast to the contracted gullet of the Greenland Whale. Throughout, the mouth is lined with a pearly white membrane. The gill-apertures are proportioned to the size of the animal, and are furnished with eyelids, the lower of which is most moveable. At a short distance behind the eyes are the external openings of the ears, sufficiently large to admit a small-quill. Not far from the posterior angle of the mouth are the swimming-paws or flukes, which are not much used in progression, but probably more as balances, and occasionally in supporting the young.

Mr. Beale gives the following as the dimensions of a sperm whale of the largest size, or about eighty-four feet in length: breadth of the head from ear to ear, thirteen feet; breadth of body from five to six feet; depth of body seldom exceeding twelve or fourteen feet; circumference seldom exceeding thirty-six feet; swimming-paws about six feet long and three broad.

The skin is smooth, but occasionally in old whales wrinkled. The general colour is very dark, deepest on the upper part of the head, back, and flukes, in which situation it is sometimes black; on the sides it gradually assumes a lighter tint, and on the breast becomes silvery grey. The hair varies in different individuals in a variety of shade, and some are piebald. Old "Bulls" have generally a portion of grey on the nose immediately above the fore-part of the upper jaw, when they are said to be grey-headed. The "black skin" in young whales is about three-eighths of an inch thick; in old whales, about one eighth. Immediately beneath the black skin is the blubber or fat, termed the "blanket," of a light yellowish colour, producing when melted the sperm oil.

Habits, Food, &c.—The bulk of the head is, as we have seen, a membranous "case," containing a thin oil of much less specific gravity than water; below which again is the "junk," which, although heavier than the spermaceti, is still lighter than the element in which the whole moves; consequently, observes Mr. Beale, the head is taken as a whole is lighter specifically than any other part of the body, and will always have a tendency to rise at least so far above the surface as to elevate the nostril or blow-hole sufficiently for all purposes of respiration; and moreover, this, a very slight effort on the part of the whale, would only be necessary to raise the whole of the anterior flat surface of the nose out of the water. At very regular intervals of time the snout emerges, and from the extremity of the nose the spout is thrown up, and at a distance apparently directly upward, and with an expired air forcibly ejected through the blow-hole, and acquires its white colour from minute particles of water previously lodged in the chink or fissure of the nostril, and also from the condensation of the aqueous vapour thrown off by the spout. In the whale, said to be Beale's in section, is projected at an angle of 130° in a slow and continuous manner for about three minutes, and may be seen from the mast-head in favourable weather at the distance of four or five miles. When the whale is alarmed or galloped the spout is thrown much higher with great rapidity, and differs much from its usual appearance. Immediately after each spout the nose sinks beneath the water, scarcely a second intervening for the act of inspiration, which must consequently be performed very quickly, the air rushing into the lungs by the diminishing spout. There is no sound caused by inspiration, and very little by expiration in this species; in short, nothing of that loud noise called the 'drawback' in the Finback and other whales. Ten seconds is occupied by a large bull sperm whale in making one inspiration and one expiration; during six of these the nostril is beneath the water. At each breathing-time the whale makes from sixty to seventy expirations, and remains therefore at the surface ten or eleven minutes. When the breathing-time is over, or, as the whales term it, the "head-turn," they stop porpoising and spouting out of an upright position; this last act is called "peaking the flukes," and those who are on the lookout call loudly when they see it—there goes flukes. The whale continues thus hidden beneath the surface for one hour and ten minutes; some will remain one hour and twenty minutes, and others only for one hour; but these, Mr. Beale says, are rare exceptions. A seventh of the time of this whale is, Mr. Beale makes out, consumed in respiration.

Small fishes are occasionally swallowed in quantities by this whale, and one has been known to eject from its stomach a fish as large as a moderate sized salmon; but the principal food of the Sperm Whale appears to consist of squids or cuttle-fishes. [Explana.]

This species is gregarious; and the herds called schools are of two kinds, one consisting of females, the other of young males not fully grown. Mr. Beale has seen as many as five or six hundred in one school. With each female school are from one to three large 'bulks' or school-masters, as they are termed by the whalers. The full-grown males almost always go alone in search of food; they are when alone very incautious and easily killed. It is the smaller, or 'forty-barrel bull,' as he is called, that makes the most desperate resistance. A large whale will yield eighty, and sometimes one hundred barrels of oil.

Mr. Beale states that the female is smaller than the male, and that she breeds at all seasons, producing generally only one at a time, but sometimes two. Nothing certain appears to be known as to the period of gestation; but the eldest Cuvier, and others, have supposed that it is not more than from four to five months; and Captain Colnett states that the young sperm whales which he saw in great numbers off the Galapagos Islands were not larger than a small porpoise. Mr. Beale's own observations coincide with those of Mr. Bennett.

Many other habits of this whale are interesting; or breaking, or leaking clear out of the water and falling back again on its side, so that the breach may be seen in a clear day from the mast-head at a distance of six miles; 'going head out,' a mode of progression which enables it to attain a considerable length; and Captain Colnett states that the young sperm whales which he saw in great numbers off the Galapagos Islands were not larger than a small porpoise. Mr. Beale's observations coincide with those of Mr. Bennett.

Geographical Distribution.—Very wide: the species has been seen in almost all seas, but it is principally found in the Southern Ocean, on the coasts of America, Japan, New Guinea, Timor, &c. Calachots have occasionally been stranded in the British Islands, as in the Frith of Forth, the Ormeys, &c.

Family Character.—Head not so convex forward as that of the Cachalot: both sides of the upper jaw furnished with transverse plates of a fibrous horny substance with loose or unwrinkled edges, being the baleen, or whalebone; lower jaw entirely unarked.

Generic Character.—No dorsal fin, which in some species is replaced by a boss or hump. In this genus, the baleen or whalebone is most highly developed. John Hunter describes this extremely elastic substance as being three or four times as broad as the perpendicular height, a term which he uses to express what constitutes hair, nails, claws, feathers, &c. It consists, he remarks, of thin plates of some breadth and in some of very considerable length, their breadth and length in some degree corresponding ten or twelve miles an hour, which they are commonly the

broadest, but not always so. The plates differ in size in different parts of the same month, more especially in the Large Whalebone Whale. They are placed, continues Hunter, 'in several rows, encompassing the outer skirts of the upper jaw, similar to teeth in other animals. They stand parallel to each other, having one edge towards the circumference of the mouth, the other towards the centre or cavity. They are placed near together in the Piked Whale, not a quarter of an inch from each other, yet within the greatest distance, yet differing in this respect in different parts of the same month; but in the Great Whale the distances are more considerable. The outer row is composed of the longest plates; and these are in proportion to the different distances from the edge of the jaw. As the plates are fourteen or fifteen feet long and twelve or fifteen inches broad; but towards the anterior and posterior parts of the mouth they are very short, they rise for half a foot or more, nearly of equal breadth, and afterwards shelf off from these portions of the whalebone, and are termed the teeth. They are termed the "toothed" or "darker" whalebone; the inner plates, corresponding to the termination of the declivity of the outer, and being shorter and shorter till they hardly rise above the gum. The inner rows are closer than the outer, and rise and extend from the gums in a straight line, and are gradually, or at least partly, divided by longitudinal slits. The outer rows, the plates of which are constantly changing, correspond to the termination of the declivity of the outer, and are shorter and shorter till they entirely pass out of sight; the plates of the outer rows laterally are not quite flat, but make a serpentine line; more especially in the Piked Whale, the outer edge is thicker than the inner. All round the line made by the inner edges, the whalebone is white, head, which is formed along with the whalebone, and wears down with it. The smaller plates are nearly of an equal thickness upon both edges. In all of them the termination is in a slanting line. If it be supposed, as the plate was spun into innumerable small parts, the exterior being the longest and strongest. The two sides of the mouth composed of these rows meet nearly in a point at the tip of the jaw, and spread or recede laterally from each other as they pass back and at their posterior ends, in the Balcena, they make a sweep inwards, and come very near each other, just before the opening of the oesophagus. In the Piked Whale there were above three hundred in the outer rows on each side of the mouth. Each layer terminates in a gradual convexity inclined to the outer edge of the mouth, answering to the gradual diminution of their length; so that the whole surface, composed of these terminations, forms one plane, rising gradually from the roof of the mouth; from this obliquity of the edge of the outer row is the whole substance of the mouth, it is formed of two layers, and so arranged that a piece of skin, of any thickness, when placed on it, forms the whole base, but not exactly, as it makes a hollow curve, which increases the base. The whole surface resembles the skin of an animal covered with strong hair, under which surface the tongue must immediately lie when the mouth is shut. The curves of the whalebone, as far as the whole edge, is of a brown colour, and a little lighter where the fish is deepest. In the Piked Whale, and is darker in the Large Whale. In the Piked Whale, when the mouth is shut, the projecting whalebone remains entirely on the inside of the lower jaw, the two jaws meeting everywhere along their surface; but how this is in their inner view and substance is difficult to say. The horizontal plane made by the lower jaw being straight, as in the Piked Whale; but the upper jaw being an arch which cannot be hid by the lower. I suppose therefore that a lower upper lip, meeting as low as the lower jaw, covers the whole of the outer edges of the external rows. The whalebone is continually wearing down, and renewing in the same proportion, except when the animal is growing it is renewed faster and in proportion to the growth. The formation of the whole surface, which is formed of the mouth, is in some parts more gradual, and in one respect similar to that of hair, horns, spurs, &c.; but it has besides another mode of growth and decay equally singular. These plates form upon a vascular substance, not immediately adhering to the lower jaw-bone, but having a broad base to fovea singular. This substance, which may be called the nidus of the whalebone, sends out (the above) thin broad processes, answering to each plate, on which the plate is formed, as the cock's spur or the bull's horn, on the bony core, or a tooth on its pulp; so that each plate is necessarily hollow at its growing end, the first part of the growth taking place on the inside of this hollow. Besides this mode of growth, which is common to all such substances, it receives additional layers on the outside, which are formed from the albumen, or vascular substance extended along the surface of the jaw. This part also forms upon it a semi-horny substance between each plate, which is very white, rises with the whalebone, and becomes even with the outer edge of the jaw, and the termination of its outer part forms the head above mentioned. This intermediate substance fills up the spaces between the plates as high as the jaws, acts as abutments to the whalebone, or is similar to the alveolar processes of the teeth, keeping them firm in their places. As both the whalebone and the intermediate substance are constantly growing, and as we must suppose a determined length necessary, a regular mode of decay must be established, not depending entirely on chance, or the use it is put to. In its growth three parts appear to be formed; one from the rising core, which is the centre; a second on the outside, and a third below the intermediate substance. These appear to have three stages of duration; for that which forms on the core, I believe, makes the hair, and that on the outside makes principally the plate of whalebone; this, when got a certain length, breaks off, leaving the hair projecting, becoming at the termination very brittle; and the third or intermediate substance, by the time it rises as high as the edge of the skin of the jaw, decays and softens away like the old cuticle of the sole of the foot when steeped in water. The use of whalebone. I should believe, is principally for the retention of the food till swallowed; and do suppose the fish they catch are small when compared with the size of the mouth.'

(Hunter On Whales.)

Example, Balena mysticetus.

Description.—Colour velvet-black, grey, and white, with a yellow tinge. Back, greater portion of the upper jaw, part of the lower, fins, and tail, black. Lips, fore part of lower jaw, sometimes a little of the upper, and a portion of the abdomen, white. Eyelids, junction of the tail with the body, part of the axilla of the flippers, &c. grey. The under the whale, the more white and grey is there upon it; some are piebald all over. The surface of the body is rather furrowed. The head is very large, forming nearly a third of the whole bulk, the under part, the outline of which is given by the jaw-bone, flat. The lips enclose the whole surface, which is without hairs. The rounded edges like a boat upside down, so as to shut in the front and upper parts of the cavity. On the most elevated part of the head are situated the blow-holes, two longitudinal apertures like the holes in the belly of a violin, and from these is issued the song of the whale. This is above three hundred of these plates of whalebone on each side of the jaw, enclosing the tongue between their lower extremities and themselves covered by the lower lip. The body is thickest a little behind the flippers, near the middle of its length, where it gradually tapers conically towards the tail, and, slightly, towards the head. There is no dorsal fin. The flippers, about nine feet long and five broad, are placed about two feet behind the angle of the mouth, and cannot be raised above a horizontal position. The horizontal tail is flat and semicircular, situated in the middle; the two lobes somewhat pointed and turned a little back-
wards. The eyes, not much larger than those of an ox, have a white iris, and are situated on the sides of the head about a foot obliquely above and behind the angle of the mouth, so that they appear to be sunk in the water, but not above it. The size of this whale has been supposed to have been greatly exaggerated by old statements. Eighty and a hundred feet were mentioned as a frequent length, and many accounts more than doubled the figure. At present, six, three, or seven feet appear to be the extreme length of a full grown Mysticete. Mr. Scoresby, who has elucidated the history of this whale as satisfactorily as Mr. Beale has that of the Sperm Whale, and who was personally concerned in the capture of three hundred and twenty-two, found none that exceeded six feet. It should be remembered however, in criticising old accounts, that the great persecution which these animals have long undergone and still undergo, while it reduces their members, is in favour of longevity.

Geographical Distribution.—The habitat usually assigned to this whale is the most extensive: thus M. Lesson states that it inhabits all the seas of the globe, especially the two poles; but it is not improbable that the Whalebone Whale or Black Whale of the South Seas, Balæna Australis, Desmoulin, Balaena Antartica, Less., which has every appearance of being distinct, and moreover of being infested with cirrhiped parasites (Tabicinella, Cornula, &c.) of different species from those which infest the Greenland Whale, has been mistaken for the last named cetacean. Multitudes of the Southern Balaena were seen by Captain James Ross, R. N., in very high southern latitudes during his last expedition.

The Common Whale, Greenland Whale, or Great Mysticete appears to be the genus of Aristotle (Hep. Anim. III. 12.): it is the Balaena Francæ and Balaena Ordinarie of the French; Gronlands Walffish of the Swedes; and Morffl Cuffredins of the ancient British.

Habits, Food, &c.—This species seems to hear acutely and swim very well in the water, such as fishing, &c. in rough weather: but a sound produced in the air, a loud shout for instance, when the whale is only at the distance of a ship's length, is disregarded. The usual rate of swimming seldom exceeds four miles an hour, but they will descend with a velocity of eight to ten miles an hour, and one of these whales when alarmed can sink in five or six seconds far beyond the reach of a human enemy. The Mysticete seldom remains at the surface to breathe longer than two minutes, during which period it blows each time. It then descends for five or six minutes; sometimes, when on its feel, for fifteen or twenty minutes. Though Mr. Scoresby states that it has no voice, it makes, he observes, a loud noise in blowing. The spout is ejected some yards high, and has the appearance of a puff of gunpowder. They blow strongest, densest, and loudest, when alarmed, or after a long stay under water.

A very considerable portion of the feeding grounds is occupied by what is termed "green water," which swarms with minute life, and has been carelessly examined and described by Mr. Scoresby. The smallness of the gullet is only fitted for swallowing small animals, such as the Clito borealis, numerous specimens of which, the Whale's Food of the Greenland Whalers, will be found in the preparation Nos. 23 A of the Physiological series of the Museum of the Royal College of Surgeons in London. This small mollusk is said to constitute the chief support of the Mysticete, and the structure and disposition of the whalebone plates, illustrated in the preceding preparations, explain how these or any other small species of animal are retained in the capacious mouth of their devourer, while the water taken in along with them drains through the interstices of the plates. When the Mysticete feeds, it swims rapidly below the surface with open jaws; a stream of water enters, and with it myriads of small marine animals; the water finds an outlet at the sides, but the thick internal hairy apparatus of the whalebone does not permit one of those animals to escape.

Nine or ten months is supposed to be the period of gestation, and the mother is so attached to her young one, or "sucker," as it is termed, that it is often struck as a snare to the affectionate parent, for she will not leave it, and falls a victim to her maternal love. Mr. Scoresby illustrates instances of this kind which cannot be presumed, much less witnessed, without great pain by any person of ordinary humanity. Such a mode of capture seems hardly justifiable, whilst it must be ruinous to future prospects.

This species is generally found alone or in pairs, excepting when many individuals are attracted to some abundant feeding ground, or to a desired locality, such as the vicinity of ice-bergs.

Utility to Man.—To the Esquimaux and the Greenlander this species is all in all. They eat the flesh and fat with indescribable relish. The membranes of the whalesmen serve them for clothing, and the thin transparent petrionemodium admits light through the windows of their huts whilst it keeps out the weather. The bones are made into props for their tents, or aids in the formation of their boats, and supply them with harpoons and spears for the capture of the seal, and greater sea-birds. The sinews divided into filaments are used as thread for sewing their dress, &c. Some have stated that pickled and boiled blubber is palatable, and that the tail, raw parched, and then fried, is agreeable eating. The flesh of the young whale is said to be by no means indifferent food. To civilized nations, the oil made from its fat or blubber, and the whalebone, have long made it a great commercial object. [Fisheries, vol. x, p. 268.]

The Greenland Whale.

To Mr. Scoresby's well-known book we must refer for further interesting and amusing particulars. The history of the Balaenoptera, or Orca, some of which grow to eighty or a hundred feet in length, may be found in the works of Lacépède, and of Baron Cuvier and M. F. Cuvier.

In the Fauna of New Zealand, published at the conclusion of Dr. Dieffenbach's work, Mr. I. E. Gray figures a whale which he is induced to regard as a new species, and names Balæna antipodan. The description is taken from a drawing engraved in the book. It is the Tuka pera of the natives. The specimen was sixty feet in length. The following cut is reduced from Mr. Gray's plate.

Balæna antipodan. (Gray.)

**Fossil Cetaceans.**

The fossil remains of cetaceans have hitherto been found in the tertiary formations only. Those bones from the Portland Stone, which were at first thought to belong to whales, proved to belong to the genus Ceratoneurus, Owen, the most gigantic of all the fossil reptiles (See Professor Owen's Report on British Fossil Reptiles). Dr. Buckland, in his Bridgewater Treatise, remarks that the seas of the Miocene and Pliocene periods were inhabited by marine Mammmals, consisting of Whales, Dolphins, Seals, Walrus, and the Laminant or Manatee, whose existing species are chiefly found near the coasts and mouths of rivers in the torrid zone. The presence of the Laminant in New Zealand adds another argument to the view that arose from the tropical character of many other animals; even...
of the latest tertiary strata, in favour of the opinion that the climate of Europe maintained a high, though probably a gradually decreasing temperature, even to the latest period of the tertiary formations.

Phytophagous Cetacea.

Cuvier figures and describes the remains of a Manatee differing from the existing species. Specimens were collected from various parts of France, and he states it to be very certain that an animal of the genus Manatus, a genus now peculiar to the torrid zone, inhabited the antient sea which has covered Europe with its shells at an epoch posterior to the formation of the chalk, but anterior to that in which the gyposm was deposited and the Palaeotherium with its contemporaneous genera lived on the soil of France. (Out. Foss.)

M. Hermann von Meyer, in his Palaeologica, notices this fossil herbivorous cetaceum under the name of Manatus. He also refer to another Manatus under the name of Manatus fossus, Harlan. (Fonna Americ. Journ. of Philad. IV.) See post, last paragraph of the article.

Zoophasous Cetacea.

Cuvier notices and figures with an accurate description the remains of a fossil dolphin approaching the Grampus and Delphinus globiceps from Lombardy, the skeleton of which was found nearly entire by M. Cortesi; and another with the remains of the lower jaw from the department of Landes. Also a fossil dolphin closely approximating the common dolphin from the same locality, and another from the calaisse grotto of the department of Oune. (Out. Foss.)

Meyer refers to these and another (Grateloup, Sbem. d. Sc. Phys. iii., s. 56, t. 36; Taylor, Magaz. d. Hist., March, 1830, s. 262) giving the following names.—Delphinus Cortesi, Delphinus macrogenius, Delphinus longirostris. (Paaleologica.) See post, last paragraph of the article.

Monodon.

Cuvier collects notices of fossil fragments of the Narwhal from Parkinson and George.; he adds, that he himself was not able to procure a piece in the cabinet of Natural History of Lyons which had formerly been in that of Penta-

Lozi. (Out. Foss.)

Ziphius (fossil only).

Cuvier founded this extinct genus, which approximates the Cachalot and Hyperoodon. A crania discovered on the coast of France, and disinterred in excavating the docks at Antwerp, and on a fragment in the Paris Museum. On these materials he rests three species, viz.—Ziphius cana-

viatus, Ziphius planirostris, and Ziphius longirostris, the remains of which he figures and describes. (Out. Foss.)

Zeuglodon.

The arrival of Dr. Harlan in this country with some of the remains of his Basilosaurus, which he and others con-

sidered to be a fossil reptile, and the permission given to Professor Owen to see the specimens of those that he had brought the latter to come to the conclusion, that the alleged Basilosaurus was not reptile, but a cetaceum. This he has satisfactorily proved in his paper read before the Geologi-

cal Society of London, in January, 1839, and published in the ninth volume of the second series of that Society's Transactions. The parts brought over by Dr. Harlan were two portions of bone belonging to the upper jaw; the larger one containing three teeth, the smaller one the sockets of two others. The microscopic characters of the texture of the teeth were strictly of a mammiferous charac-

ter, and the nature of their investing substance limited the comparison of them with those of the few mammals in which the teeth are devoid of enamel. Among these are the Eolitans, Mammuthus, Mammuthus, and its con-

gener, the Morse, the Dugong, and the Cachalot. It is to the teeth of the Cachalot and Dugong that those of the so-

called Basilosaurus offer the nearest resemblance, and Professor Owen conceives that its position in the natural system was in the same order, intermediate between the Cachalot and the herbivorous species. Dr. Harlan, who examin-

ed with the Professor the sections of the various teeth on which this conclusion was founded, himself suggested the propriety of substituting another generic name more

in accordance with the true affinities of the animal. In recapitulating the chief points of evidence which, when Professor Owen read his paper, could be brought to bear on the question of those affinities, he observes that it may be stated that the form of the humerus, though unlike that of any known vertebrate animal, yet approaches much closer to the mammanian than to the saurian type; the vertebrae which Professor Owen examined not only pre-

sented a strictly mammanian organization, but also the cetaceous modification of that type. The teeth being of two kinds, some with single, others with double fangs—being freely implanted in distinct sockets,—consisting only of dentine and cementum, hence these presenting an inti-

mate structure most closely resembling that of the same constituents of the teeth of certain aquatic mammals, as the Dugong.—afford, the Professor observes, a body of evidence which is conclusive as to the class of Vertebrata to which the extinct animal belonged, and point with a high degree of probability to the order and family to which it bore the closest affinities. 'The teeth,' says Professor Owen in conclusion, in their combination of an exagger-

ated condition of the conjugal form—which is but in-

dicated in certain teeth of the Dugong, with two distinct fangs, in their oblique position in the jaw, and the irregu-

lar intersepses of their alveoli,—present very striking peculiarities; and when to these dental characters we add the remarkable and abrupt contraction of the distal end of the humerus, which is in the teeth freely provided with an arti-

culating surface for a ginoglynd joint, and its remarkably diminutive size,—a cetaceous character, which likewise is here carried to an extreme,—and when we also consider the dense laminated structure of the ribs, and the third exaggeration of a cetaceous structure in the extreme elonga-

tion of the body of the caudal vertebrae,—we cannot hesitate in pronouncing the colossal Zeuglodon to have been one of the most extraordinary of the Mammalia which the revolutions of the globe have blotted out of the number of existing beings.

In the American Journal of Science for April, 1843, is a Notice of the discovery of a nearly complete Skeleton of the Zeuglodon (Zeuglodon) of Owen (Basilosaurus of Har-

lan) in Alabama; by S. B. Buckley, A.M.

The entire length of the skeleton, including the head, is described as nearly seventy feet, and was imbedded in a marly limestone soil on the plantation of Judge Creagh, the same gentleman who had forwarded the bones to Dr. Harlan, some of which were brought by the latter to London as above noticed. This discovery entirely corroborates the conclusions to which Professor Owen was led in the memoir above quoted. Bones of this gigantean fossil cetacean have been also found near the Washita River in Louisiana, and have been seen in Washington County, Mississippi: from

P. C., No. 1717.
 thence, Mr. Buckley adds, they have been found in several places as far east as Claiborne, on the Alabama River. The skeleton is now at New York.

*Balaenoptera.*—Cuvier figures and describes the skeleton of a fossil whale, which he considers to have been a subgenus of *Balaenoptera,* or Orcaul, found in Lombardy by M. Cortesi, on the east flank of Monte Pulgnacuso (Apenines). He says that the skeleton calculated from the entire length of twenty-one feet, French, observing that if the animal was adult, it was a very small *Orcaul.* Another skeleton of the same species, not more than twelve feet five inches long, was also discovered by M. Cortesi in similar beds and in a branching valley, near a small stream which falls into the Chiavena, one of the tributaries of the Po. *(Ost. Foss.)*

*Balaena.*—Numerous remains of *Balaena* have been found in the tertiary formations. Cuvier mentions a considerable number of ribs, vertebrae, and other parts, which were found at the Rue Dauphine at Paris, in 1779. Daubenton came to the conclusion that the whale to which it belonged must have been a hundred feet long; but Cuvier on satisfactory calculations reduces the length to sixty, and states his opinion that there are some places which a whale from Dr. Mantell detected the remains of *Balaena* in Sussex (Brighton Chiffs). A narwhal and porpoise appear to have been found in alluvial deposits of the district noticed in the *Geology of the South-east of England.* We are informed by the Edinburgh Phil. Journal, for instance, which have occurred in Scotland, and to Hermann von Meyer's *Palaeologica,* *(Balaena;* Wallfisch,* p. 100,* for reference to authorities on this subject.

Described by Brandon in 1763, *Batresaurium Ratktkii,* and which occurs in the tertiary limestone of Taman, has, we have reason to believe, attracted the notice of M. Murchison, Count Keyserling, and M. de Neurville, as a new link in the animal series, and more allied to the herbivores than to the Delphinia.

Whalley. *(Lancashire.)*

*Wharf.*—A place constructed or set apart for the loading and unloading of goods. In this sense the word includes the quays or docks and landings by which goods are unloaded and landed by cart, or floated, and to which vessels are referred for wharfage, and which is used for the purpose of storage, and sometimes of repair. Wharfs in docks and similar situations are made legal by special acts of parliament, as the London Docks, &c., and there are some places which are referred to as wharfs by the Custom-House of London, and which have been used as wharfage, as at CHEPSTOW.

For the use of a wharf certain rates of compensation are usually charged, which are called wharfage, and the act 22 Car ii. c. 11, (with repeals) and subsequent acts. The sea-beach, or natural ground on the banks of a river or canal, is not a wharf. Wharfs in docks and similar situations are made legal by special acts of parliament, as the London Docks, &c., and there are some places which are referred to as wharfs by the custom-House of London, and which have been used as wharfage, as at CHEPSTOW.

(Ellis's *Laws of the Customs,* vol. ii, p. 90; McCulloch's *Dictionary of Commerce.)*

*Wharton,* Thomas Wharton, Marquess of. The son of Philip, Lord Wharton, one of the few noblemen who adhered to the parliament in the civil wars, and who is characterised by Clarendon as 'a man very fast to that side,' by his second wife, Jane, daughter and heiress of Arthur Goodwyn, of Upper Winchendon, in Buckinghamshire, Esq., Mr. J. T. Rutt, in a note to a edition of Burton's 'Diary' (i. 367), makes it clear that he is the son of whom Lord Wharton's lady is recorded in the Diary to have been delivered on Tuesday, 13th January, 1641—an event which his lordship's relation, Sir Thomas Wharton, is stated to have related to the writer, with great joy; but this we apprehend must be a mistake.

*WHA* 202

Wharton. *(Rev. Henry.*)

Wharton, Rev. Henry, was born 9th November, 1615, at Worstead in Norfolk, the son of Mr. Edmund Wharton, the descendant of an antique family, and afterwards rector of Saxlingham in the same county, was then vicar. After being taught Latin and Greek by his father, he was admitted to Christ Church, Oxford, 2nd February, 1627, and Michaelmas in the same year was chosen to one of the scholarships...
 founders by Mr. Matthew Stockys, who was his
grateful. Having taken the degree of B. A. in 1684, he
sted in his college till 1688, when he was taken into
employment of Dr. William Cave, then engaged in
the compilation of his 'Scriptorum Ecclesiasticorum Historia
Literaria,' in which Wharton assisted him not only as an
assistant in the English histories, but also in the
arrangement of materials, that a dispute afterwards arose as to his
cleim to be considered the author of a considerable part
of the work. Cave himself acknowledges his obligations in
large terms in his Preface; but after Wharton's death he
addressed his 'Epitome of the History of the Church,' which
printed in Chalmers' 'Biographical Dictionary,' in con-
truction of an account of the matter which Wharton had left
behind him. The publication of Cave's work (in 1689)
רה immediately made Wharton's name known, and brought him
lute reputation as a young man of remarkable talents
and acquirements. The year before it appeared he had
been ordained deacon, and had also taken his degree of
M.A., and he was now sought out by Dr. Tenison, then
vicar of St. Martin's, afterwards primate, who employed him
'to according and edit manuscripts of 'The Incurable
Scepticism of the Church of Rome,' written by
Jean de la Placectte, the French Protestant divine, which
it was thought desirable to make public in an English
dress. He was also, on Tenison's recommendation, en-
gaged by the London Printing House, and his name therefore
is left
Dish, Tenison, which was
published in the same stroke. In 1688, he
сollated the following year both to the vicarage of Min-
ster in the Isle of Thanet, and to the rectory of Chatham.
The catalogue of the works which he wrote or compiled, or
in the publication of which he was concerned from his first
appearance, is too long to be here extended, but his
writings, which he continued to publish or edit even before he had taken priest's orders,
tell of the kind of his character. In life, though not
fixed to his Sermons, and, abstracted thence, in the 'Bi-
graphia Britannica.' They were principally directed
against popery. The most important was a quarto volume,
entitled 'A Treatise of the Celiacy of the Clergy, wherein
the Rise and Progress are historically considered,' which
appeared in 1688, the imprimatur being dated 3rd
November, 1687. In 1691 he brought out at London, in two
volumes, folio, his great work, entitled 'Anglia Sacra,'
being a collection of original histories of archbishops and
bishops, from the earliest times to the year 1540. In this undertaking his patron was
Bishop Lloyd, who appears to have generously defrayed
all the expenses of transcribing the manuscripts and printing
the work. Unfortunately very much of it has been
lost by fire; but what is to be seen appears to be a
masterly effort of the printer and of the amanuenses; but the original matter
that Wharton has supplied evinces a great command of
antiquarian learning; and of many of the pieces in the
collection there is as yet no other edition. The 'Anglia
Sacra' is interspersed with all its defects, still retains a
value.
In 1692 Wharton published, in 8vo., 'A Defence of
Pluralities,' which was held to display great ability. In
1693 he edited, in a 4vo. volume, some hitherto unpub-
lished works of George Whitefield, entitled 'Opera quaedam Theologiae,' &c.; and the same year,
under the fictitious name of Anthony Harmer, he pub-
lished an 8vo. pamphlet entitled 'A Specimen of some
Errors and Defects in the History of the Reformation of
the Church of England,' which was, however, not
published till 1740.
D.D.' Burnet replied, acknowledging the ability of his
assistant, but complaining of his bitterness and bad
temper; and Wharton did not continue the contro-
versy. In 1695 appeared another of the most elaborate
and learned of the works of that period, which, though
brought forward in the 'History of our ecclesiastical
history—the first volume, in folio, of
'The History of the Troubles and Trials of Archbishop
Laud.' This is Laud's own account, written during his
imprisonment in the Tower, accompanied with his Diary of
his imprisonment, which was written about the same time,
which had been placed in Wharton's hands by Archbishop
Sancroft a few days before his death. A second volume,
consisting of further collections relating to Laud, was left
ready for the press by Wharton, and was published under
his father in 1703.
Wharton died at Newton in Cambridgeshire, worn out
by his labours, on the 5th of March, 1695. Two octavo
volumes of his Sermons were printed after his death; and
his papers, among which were several transcripts of old
manuscripts, which had been purchased by Archbishop Tenison, and are now in
the library at Lambeth. The second edition of Cave's
'Historia Literaria,' printed at Oxford, in 2 vols. folio,
1746, 1748, is enriched with many additions from Wharton's manuscripts.

WHARTON, PHILIP WHARTON, DUKE OF, was
the son (we believe the only son) of Thomas, Marquess of
Wharton, and was born in December, 1698. Having early
shown great quickness of parts, he was carefully educated
at Eton, and admitted as a pensioner of Trinity College, his
ambition was to make himself both a great orator and a great
patriot; the latter term meaning in his lordship's notion
not only a pure Whig in politics, but further, it would seem,
'a Presbyterian in religion. Either the training he received,
or, possibly the natural whig, which he had come
into the world, proved more favourable to the intellectual
than to the moral progress of the boy. His first folly was
an early one, his getting himself married clandestinely at
Tideway, when he was scarcely sixteen, to the daughter of
Major-General Holcroft, of Trent, who was a girl of
much too much, that it is said to have killed him in six
weeks. The old Marquess died 12th April, 1715; and the
Marchioness, also, it is affirmed, killed herself in effect by
her husband's death. He was, however, the father of a
son, who was born in the course of the next year. Yet it is
admitted by Wharton's biographers that, although the match he had made was
'so ways suitable to his birth, fortune, or character, and
far less to the great views which his father had of
disposing of his son in such a manner as would bring a
considerable addition to the fortune and grandeur of his
illustrious family,' the lady was unobjectionable, except
upon the score of the inequality of her condition, and 'der-
served infinitely more happiness than she met with in this
ill-fated connexion.' He was married again, shortly after the
marriage; in the beginning of 1716 the Marquess, probably in obedience to directions left by his
father, went abroad with a French huguenot governor to be
educated or confirmed in strict Presbyterian principles at
Geneva. In passing through Germany, he was
gratified by receiving an order of knighthood from some
petty court; he also immediately began to run in debt;
his Huguenot governor only disgusted him by his 'dry
moral precepts and the restraints he endeavoured to lay
upon his pupils.' He returned to France, and after a
brief space, cutting all entanglements, he left the
Huguenot behind, and, 'as if he had been flying from the
plague,' set out post for Lyon, where he arrived on the
10th of October, 1716.
The next proceeding was to write a letter to the President, declaring that he would
forward with the present of a fine stallion; the
Chevalier in return sent him to his court, where he spent
a day, and, it is said, accepted from the sol-daissant
king the title of Duke of Northumberland. After this he
presented himself in Paris, where he visited the court of
James II. at Saint Germain, and borrowed 2000l. from her;
without, however, declining the attentions of the English
ambassador, Lord Blair, at whose table he repeatedly dined.
When, however, the occasion to get the money failed, he
was obliged to pawn her jewels to raise it, he is asserted
to have employed it in promoting the interest of his
family in England: at the same time he told a friend
who remonstrated with him, that till he could repay what
he had borrowed and not Germania, he must then
return; when that obligation was discharged he would return to the
Whigs. 'We have heard it credibly reported,' says his
original biographer, 'that it was the too great strictness
of his trustees, particularly of the Lord L—re, who was
very much displeased that he did not make him arrangements
anyway suitable to his quality and estate, that first drove
him into those measures which afterwards proved so fatal
and destructive to him. We have also had it from good
hands, that it was the great antipathy he conceived against
the noblemen of his own persuasion, and the care, that gave the Marquess a sort of aversion even to
his principles, and made him in a manner resolve not to
be of the same side with him.'
Having signalized his stay in Paris by sundry extravagances, he returned to England in December; but soon after set out for Ireland, where he was immediately allowed to take his seat in the House of Peers, although as yet only in his eighteenth or nineteenth year. Whether he had purchased this indulgence by any engagement with the port the government does not place on the book that side with all apparent sincerity and zeal, and speedily raised himself to such distinction by the figure he made in debate, that, under age as he still was, it was thought proper to appoint him to the highest offices. He was, on the 20th of January, 1718, he created Duke of Wharton. If we put aside those bestowed on members, legitimate and illegitimate, of the royal family, this was certainly the most extraordinary creation of the government. He was no more a politician and is not even regarded as the most remarkable passage even in Wharton's singular career. Notwithstanding the practice which then prevailed, of conferring that dignity with much less reserve than at present, the attainment of it in such circumstances makes a strong impression which the talents of the young nobleman made at his first appearance on the political stage.

It was probably not till after he had attained his majority, early in 1720, that he took his seat in the English House of Lords. The same year he was chosen a member for Bassetlaw, but rejected the motion to take the bill which the debates on the 5th of April in that year. Up to this time he is said to have continued to support the ministry; but he now warmly joined the opposition to the great government measure of the South Sea Bill, in the debate on which he was not without some effect. He was one of those who, on this occasion, took place and credit to the King of Spain, he was appointed by the Conde de las Torres one of his aide-de-camp. Here, we are told, he was often in the trenches, and exposed himself wherever any service was going forward; but his conduct appears to have been of a management and bravado of real gallantry. 'He went one evening,' it is related, 'close to the walls, near one of the posts of the town, and either called to, dared, or threatened the soldiers of the garrison.' They asked who he was, he told them he was a colonel of regiments. The Duke of Wharton: 'and, though his grace appeared there as an enemy, they suffered him to return to the trenches without firing one shot at him; had they done otherwise he must inevitably have perished.' The only thing said after this was, 'Oh, what a fine man!' and that the bill might pass, he delivered a long and able speech, a full report of which was soon after published. This is the last speech of the Duke of Wharton's that is noticed in the "Parliamentary History." His estate, worth, it is said, 16,000l a year when he came to it, had by this time become so involved, that his property was placed in the hands of trustees, for the benefit of his creditors, and he was allowed only 1200l per annum. He now, perhaps in the hope of making money by the speculation, set up a bank and opened it, and the country gentlemen of himself made a member of the Cash-Chandler's company in the city of London, that he might speak and vote at common-halls and other civic meetings. But he soon got tired of that unprofitable work, and giving out that his intention was to return for a few years, he went off to the continent, apparently in the early part of the year 1724. Proceeding first to Vienna, he made a distinguished figure at that court for a short time; then he set out for Madrid, where, says his biographer, 'his arrival alarmed the English minister so much, that two expresss were sent from Madrid to London, upon an apprehension that the duke was received there in the character of a minister himself, upon which his grace was soon taken under the protection of the king.'

This order he entirely disregarded: "His grace," says one account (Salmon, in 'Chronological Historian,' under date of 10th June, 1726), "being in a coach when it was delivered to him, contemnuously threw it into the street with his boot; and, signing himself, "a Roman Catholic." He 'endeavoured,' continues the writer of his life, 'to stir up the Spanish court not only against the person that delivered the warrant, but against the court of Great Britain itself, for exercising an act which was not only a breach of his majesty's treaty, but the subversion of his own supremacy, and the diminution of his Catholic Majesty's kingdom. After this he acted openly in the service of the Pretender, and appeared at his court, where he was received with great marks of favour.'
Some time after he is stated to have been in garrison at Barcelona, where he got into a quarrel with the Marquess de Rubire, governor of Catalonia, the end of which was that he retied with the fleet to Barcelona, but to repair to his quarters at Lerida. On this, we are told, giving way to melancholy, he fell into a deep consumption; so that, by the beginning of the year 1731, he had lost the use of his limbs, and was not able to walk from his bed to the table without assistance. After about two months he rallied somewhat, from drinking a mineral water in the mountains of Catalonia; but in May, having gone with his regiment to Tarragona, he became again as ill as ever; and, going back to the mineral spring, was again improved till he got to Lerida. This seeming a most astonishing fit to which he had for some time been subject, in a small village, and was utterly destitute of all necessaries, till some charitable fathers of a Bernardine convent, which happened to be near the place where he lay, hearing of his miserable condition, offered him what assistance their house afforded. After languishing in the convent for a week, he died there on the 31st of May, 1731, and was buried the next day by the monks in the same manner in which one of themselves was, and have been interred. His widow survived, in obscurity, till February, 1777, when she died in London, and was buried in Old St. Pancras Churchyard.

The account from which the preceding facts are chiefly derived was originally published in 8vo. at London, in 1731, under the title of 'Memoirs of the Life of His Grace Philip late Duke of Wharton, by an Impartial Hand.' It is prefixed to two octavo volumes published in 1722, entitled 'The Life and Writings of Philip, late Duke of Wharton,' but the first page of the eighth volume is one of the 'True Briton,' and the speech on the bill of pains and penalties against Atterbury, the paging of which is a continuation of that of the 'True Briton,' although it has a title-page of its own, and was published in 1727. There is another publication, in two volumes, 8vo., without date, entitled 'The Poetical Works of Philip, late Duke of Wharton, and others of the Wharton Family, and of the Duke's Intimate Acquaintance, particularly Lord Bolingsroke, Dean Swift, Lord Chesterfield, and the Hon. Mrs. Wharton, &c.' These two volumes however appear to have been all printed in 1727 (before the duke's death), with the exception of only this general title-page and a Life of the duke, which is substantially the same with the noticed above, and is here stated to be 'communicated by a person of quality, and one of his grace's intimate friends.' The volumes contain very little that is even attributed to the duke; but in the second are some letters in prose, addressed to Lady Wharton, his father, then in his 91st year, and the author of the 'Complaints and Sentiments of Jeremiah.' It is said that Ritson had at one time an intention of collecting and publishing the poetical productions of the Duke of Wharton, which however probably would not have been usually known, for the duke is per

The wheat of the Mediterranean climate, have looked upon all the cultivated wheats as mere varieties. There are however three principal varieties, so different in appearance that they elicit peculiar names. These are the hard wheats, the soft wheats, and the Polish wheats. The hard wheats are the produce of warm climates, such as Italy, Sicily, and Barbary. The soft wheats grow in the northern parts of Europe, as in Belgium, England, Denmark, and Sweden. The Polish wheats have been grown in the country from which they derived their name, and are also hard wheats. It is from their external form that they are distinguished from other wheats. The hard wheats have a compact seed nearly transparent, which, when bitten through, is short, and shows a white flour within. The soft wheats have the grains cultivated in Britain; they have an opaque coat or skin, and which, when first reaped, give way readily to the pressure of the finger and thumb. These wheats require to be well dried and hardened before they can be conveniently ground into flour. The Polish wheats have a long chaff which is much longer than the seed, a large oblong hard seed, and an ear cylindrical in appearance. It is a delicate spring wheat, and not very productive in the climate of England; hence it has only been occasionally cultivated by way of experiment.

The following cuts represent some peculiar varieties of wheat. The first is a compound ear, produced by very luxuriant vegetation, and is common in Egypt. The second is a slender wheata which the body of which is attached to the grain as to be separated only by passing through a mill. It is an inferior variety, but grows in less fertile soils. The third is the Polish wheat, with very long chaff and hard grains. The fourth is a variety which only has one end of chaff, which is a very peculiar and is not much cultivated. The fifth is common soft bearded wheat. If the awns of this kind are obliterated, it forms our common soft wheat. The circumstance of awns seems not to affect the hard wheats of the different species. They differ so much in length that the varieties of smooth-eared and bearded wheats run insensibly into each other.

The hard wheats contain much more gluten, a tough viscid substance which is very nutritious, and which, if converted into alcohol, would form a powerful agent in fermentation, or rising, as it is called, of the dough, which is essential to good light bread. The quantity of this varies with the soil and climate, from 5 per cent. in some soft wheats, to 30 per cent. in the hardest and most transparent. It is this quantity of gluten which causes the Italian wheats to be used exclusively for the rich pastes which form so large a portion of the food of that nation. The soft wheats contain the greatest quantity of starch, which fits them for the vinous fermentation, by which wines are produced, and which, with water and alcohol, for brewing or distilling, therefore, the soft wheats are the best. The distinction between the winter and summer wheats is one which arises entirely from the season in which they are sown. They differ very much in rising, and gradually accelerating or retarding their growths. The difference in colour between red and white wheats is owing chiefly to the soil; white wheats gradually become darker and ultimately red in some fertile soils, and the red wheats lose their colour and become first yellow and then white or rich, light, and mellow soils. It is remarkable that the grain sooner changes colour than the chaff and straw. Hence we have white wheats with red chaff, which on the foregoing principle is readily accounted for. The chaff retains the original colour when the skin of the grain has already changed to another. We state this on our own experience. The soil best adapted to the growth of wheats is a deep friable soil, with a dry subsoil. If this is not so naturally, it must be drained artificially, to ensure good crops of wheat. In such a soil, wheat may be sown every third year, with proper intermediate crops. Formerly the preparation for a crop of wheat was a clean fallow, followed by a certain addition of manure, the remark of which were thought sufficient for a crop of barley or oats; after which the fallow recurred. It was soon found out that, by this means, a crop of wheat would never go beyond an average; for it was then to be as much as possible the goal. But when manure was hurried on the land, the wheat failed, by being laid before it arrived at maturity. Thus a limit appeared to have been set to its increase. New modes of cultiva-
have shown that this was not without its remedy, and that it was recent manuring which caused the wheat to lodge; but that an increased fertility, produced by judicious preparation, enabled the land to bear crops of wheat far superior to what it ever could before. Wheat requires a soil in which the organic matter is intimately mixed with the earthy ingredients; where it can have a firm hold by its roots, and can at the same time strike the fibres of them downwards, as well as around, in search of food. When it meets with such a soil and is deposited at a proper depth, it vegetates slowly, pushing to the surface one cylindrical filament, while numerous fibres strike into the soil from the seed. These supply the plant with regular nourish-

ment, and in due time a knot is formed at the surface of the soil, from which several roots and stems branch out. This is called the tillingering of the wheat. The new roots near the surface soon become the chief source of nourishment, and in a rich compact soil, where there is room, numerous stems arise, forming a tuft, and each of those in turn bears a large ear well filled with seeds; so that from a very moderate quantity of seed a great return is produced. The strong stems supporting each other are well able to resist the effect of storms and rains, which would lay weaker plants level with the ground. The effect of abundant manuring immediately before the seed is sown is to produce too rapid a growth, weakening the straw, and increasing its quantity at the expense of the ear, which does not attain its proper development. This is called running to straw. All strong manures which contain many saline particles have this effect; which is corroborated by late experiments with salt-petre, nitrate of soda, and other saline compounds. They produce more straw and less corn, and hence are not found of the same use, when applied to crops which are cultivated for their seed, as they are for grass.

A certain portion of nitrogen is essential to the production of good wheat, as that element enters into the composition of the gluten, which will be found to abound in proportion as nitrogen exists in the soil, or can be supplied from the atmosphere. The experiments of Liebig have shown that the nitrogen of the atmosphere will not enter into the substance of plants, except in the form of ammonia, and hence the efficacy of manures has, of late, been estimated by the quantity of ammonia which they can produce. This theory however requires to be confirmed by experience, before it is at once adopted without limitation. Decayed vegetable matter, or humus, seems essential in a good wheat soil, and it may, in the slow progress of its entire decomposition, when it is continually absorbing the oxygen of the air, have some chemical effect on the nitrogen also, so as to make it of use in the vegetation, whether by first forming ammonia, or in any other way. Further experiments may perhaps throw a light on the subject. It is well known however that, provided a soil be compact, its fertility is very nearly proportioned to the quantity of humus which it contains, especially if there be calcareous earth or carbonate of lime in its composition. Lime has been often considered as the most efficacious manure for wheat, even more than dung. As long as there is organic matter in the soil, lime acts beneficially, and the richer the land which does not contain carbonate of lime already, the more powerful the effect of liming. But experience has proved that lime has little effect on poor soils, until they are first manured with animal and vegetable substances. To produce good wheat then, the land should be gradually brought to the proper degree of fertility, by abundant manuring for preparatory crops, which will not suffer from an over-dose of dung, and will leave in the soil a sufficient quantity of humus, which is blended with it, for a crop of wheat. Clover is a plant which will bear a considerable forcing, and so are beans, and both are an excellent preparation for wheat. The roots left in the ground from a good crop of either, decay slowly, and thus furnish a regular supply of food for the wheat sown in the next season. Potatoes also admit of much forcing, but the necessary loosening of the soil for this crop renders it less fit as a preparation for wheat. Experience has fully proved that, as a general rule, it is better to sow barley and clover after potatoes, and let the latter be succeeded by wheat.

Improved chemical analysis has discovered various substances in minute quantities in the grains and straw of wheat; and this has led to the doctrine that these substances, though essential to its formation, must be excellent manures for it, if they do not already exist in the soil in sufficient quantities. Most of these substances are found in all soils which contain a due proportion of clay. Silica in a very minutely divided state, and probably in combination with alumina or other substances most important to give due strength to the straw; and hence, in some soils, potash or wood-ashes which contain it may be advantageously used as manures to the young clovers preceding the wheat. The analysis of the ashes of grains of wheat chosen out of the ears, by Theodore de Saussure, who is generally considered an excellent authority, gives the following results:
Potash 15
Phosphate of potash 32
Muriate of potash 16
Sulphate of potash a trace.
Earth phosphates 44.5
Silica 5.5
Metallic oxides 0.25
Loss 7.5

The analysis of the ashes of the straw gave the following result:

Potash 12.5
Phosphate of potash 2
Muriate of potash 3
Sulphate of potash 2
Earth phosphates 6.2
Earth carbonates 3.5
Silica 51.5
Metallic oxides 1
Loss 7.5

The analysis of the ashes of the whole plant, when in blossom, gives of—

Soluble salts 41
Earthy phosphates 10.75
Silica 20
Metallic oxides 0.5
Loss 21.5

By comparing these results it will appear, that from the time of flowering to the maturity of the seed a portion of the soluble salts is converted into earthy phosphates; that silica accumulates in the straw, but not in the grain; and as potash is the principal means of rendering the siliceous soil porous, it may be made to give a very good return in soils which would otherwise have been thought fitted only for the growth of rye and oats. But then the texture and composition of these soils must have been greatly improved by judicious tillage and manure. When the heavy soils are properly ploughed and pulverized to render them mellow, the lighter are rendered more compact by marling, where this can be readily done, by adding composts in which the principal earth is compost, and especially by such plants as have the subsoil and long roots by which the soil is kept together, such as clover, lucern, sainfoin, and other grasses. If these plants have been well manured, and cover the ground well, keeping in the moisture, the soil will have become sufficiently compact to bear wheat. One ploughing is then quite sufficient, and if a heavy land-presser is made to follow two ploughs and press in the furrows, so as to leave deep smooth drills eight or nine inches apart, in which the seed can find a solid bed, there will be every probability of a good crop of wheat, which will not come up in regular rows, the roots being at such a depth as to run no risk of wanting moisture till the stem has arisen to its full height, and the ear is formed: a few showers at that critical time will make the grain swell, and insure a good crop.

On some soils it may not be judicious to attempt to sow wheat; but these are the poorest loose sands, which naturally would bear only oats and buckwheat; on these, unless they can be abundantly manured, it is much better to sow rye. When wheat is sown on light soils in good heart, it grows vigorously in spring, if it has not been injured by the frost, which is very apt to raise up the roots and throw them out of the ground. The driving of sheep over the field presses the roots into the ground, and prevents this throwing out; but a vigorous growth of straw is not always a sure sign of a good crop at harvest, as many farmers know by sad experience: what would be advisable in heavy soils is not always so in lighter. A heavy rolling in spring after a light harrowing is very useful at a time when the surface is moist. It closes the pores and checks the evaporation: and the tighter the surface can be made the better chance there is of a fair crop. The Norfolk rotation, as it is generally called, in which wheat is sown after clover, is the only one well adapted for wheat on light soils. The wheat will put abundantly for the turnips, and the land being freed from weeds, the barley which follows is generally a good crop; and the clover, which is sown in this, is trampled in the reaping and carrying of the barley: and there is only one ploughing from the time of sowing the clover to the sowing of the wheat. If this be dabbled on the turnedeward of the clover, the land will receive another treading by the dibblers, the seed will be regularly deposited at a proper depth, and the preparation of the land is more likely to produce good wheat. On heavy soils the process must be varied; the surface, instead of being rendered more compact, will often be so bound as to require to be stirred by harrowing or hoeing before the wheat plant can properly erect itself. If, for example, one has good crops of wheat, he must not rest satisfied after he has ploughed, manured, and sown: he must watch the growth of this important crop daily, and use the means which experience and observation have suggested to assist the growth and to remove the causes of failure.

In heavy soils nothing is more detrimental than excess of moisture. Even in well-drained fields the water will stand too long in the furrows if there is not a proper outlet for it. The furrows should be well cleared out with the spade as soon as possible. The dibbling is often sufficiently done to prevent earth being thrown evenly over the surface of the stitches, and not left in an unsightly ridge, which crumbles down with the furrow at the first frost. In proper places and at regular distances deeper water-furrows should be dug out of the plough-soil, and plugged with a deep-tended line; and this should then be finished as is said above: so that if a heavy fall of rain should come suddenly, the water will have a regular course and outlet into the ditches which lie in the lowest part of the land, which is back-breaking to the farmer, and every time tending to produce moisture. It is chiefly in spring and when snow melts that there should be a daily inspection of the wheat-fields. An experienced eye going along the bottom of the ridges of a large field will discover at once whether there is any stoppage of the water; and by means of a spade or shovel it will be remedied with little trouble. When the surface binds, as it does in some soils, and prevents the access of air to the roots, the land is harrowed or hoed, and in a few days the effect will be apparent.

Soils which lie over a porous subsoil, or which by artificial draining have been so dried and mellowed that horses can go over the land at all times, without making such an impression as will retain water if it rains, may be driven over with drawn carts, without the least harm to the surface. There is the convenience of ploughing with a fixed turnfurrow; and thus a considerable portion is made productive which would be taken up by furrows, and perhaps produce weeds. But if the soil is of a tenacious quality, easily compressed when moist, and horses cannot safely be answered to have over it when wet, it is absolutely necessary to divide the land into stitches, or beds with furrows between them, in which the horses can walk while they draw harrows or any other implement over the land. All the implements should be so constructed that, if they have wheels, these may run in the furrows, so that nothing will disturb the evenness of the stitches, which should have a very gentle slope from the centre towards the two furrows which bound it. For spring crops this is not so essential, although it is advisable not to drive over the land when barley and clover are sown, because, when the surface is laid in double stitches, as is sometimes done, it is not very easy to lay it in narrow stitches again, at one ploughing, for wheat. No doubt a very expert ploughman can do so, but not to the advantage of the ploughmen if men are on the same farm. Even in very light soils, as in Flanders, narrow stitches with deep intervals are thought most advantageous.

It is a very common notion that good wheat and bean land are well adapted to the growth of roots, especially of such as are usually fed off the land by sheep, because the treading of animals is injurious in winter and spring, when these crops are usually wanted; and if they are catted off, the wheels and the horses make such impressions as are equally detrimental or more so. But all roots, even the
white turnip, will grow luxuriantly on heavy soils well prepared and manured; and they may be so managed as to be taken off before the winter, or even very soon after wheat harvest. The bulbs will not be so large, but they will be more succulent, and may be kept in various ways till they are wanted for the cattle. The land being ploughed immediately on the removal of the turnips, will, or, when mellowed by the winter's frost, may be sown in spring with beans, barley, or oats. The manure will be incorporated with the soil, even if it has been thrown on it, and the seeds of weeds, and thus can only be recommended on very compact soils. If the root crops are well cleaned, fallows may be avoided, or, at least, recur very seldom, and then only when root weeds have been neglected.

When the wheat has blossomed, and the grain in the ear is fully formed, it should be watched, and as soon as the seed feels the consistency of tough dough, and the straw is dry and yellow below the ear, it should be reaped. The skin of the ears, and the stalks are of a more palish green, and the wheat harden readily by mere drying, while the straw is better fodder for the cattle. It is found by experience that the increase of flour by adopting this method is very considerable.

It was the custom of our forefathers to cut the straw half, or two thirds, off before the grain was mature; but this was, that less room was required in the barn, and no seeds of weeds were carried there in the straw: but the loss of half the straw, which might have afforded litter or fodder for cattle, was overlooked: and if the weeds were not taken out before sowing, they could not be afterwards got rid of. Giving a little more trouble in winnowing and sifting the corn, they were left to shed their seeds on the land, and thus perpetuate its foulness, or add much to the labour of weeding the succeeding crops. The stubble or halms had been torn up, and the wheat only left standing, and this ploughed, and although this might make a very good shelter for cattle in a yard, when made into halm-walls, as they are sometimes called, there was a great loss of labour in weeding the yard over the flat straws. It is, therefore, the most approved mode of reaping now is that which is called an 'in and out' bagging in Middlesex and Surrey (Harvest), but the most expeditious is mowing, which, by means of a cradle or scythe, may be done so regularly as to allow all the corn to be tied up in bundles, or to have all the weeds cut up with the corn, and when the whole is threshed, the seeds of the latter are winnowed out and burnt: thus they cannot infest the land, and there is double the quantity of straw to convert into manure—a matter of great importance. Mr. T. S. Henslow, in his 'Fruits', of the choice of the seed on turnips in the yard, chiefly for the sake of their dung.

The choosing of wheat for seed is a matter of great importance. Some farmers like to change their seed often; others sow the produce of their own land continually, and have found that their soil and their wheat are improved by this. The fact is, that it is not always the finest wheat which makes the best seed; but it depends on the nature of the land on which it grew. Some soils are renowned far and wide for producing good seed, and it is well known that this seed depends, in some degree, on the state of the ground into which the seed is sown. Many places have been noted for this peculiarity; and among them we may mention the parish of Burywell, in Cambridgeshire: the wheat which grows there is most sold at a price considerably above the average. It has been ascertained of the owners of this wheat that the best adapted seed for this soil is the glum, the best adapted to the land is the seed with the slender, the most suited to the land is the seed which contains most gluten is preferred, as we observed before; but to produce a perfect vegetation, there should be no excess of this substance, nor any deficiency. The seed also should have come to perfect maturity. This latter condition is not attained by being mellowed over a couple of wood or a cask, without untying them, by which means the ripest seed falls out. The proportion between the starch and gluten is easily ascertained by carefully washing the flour when the wheat has been ground. It is most convenient to tie up the flour in a cloth, which, shaken and beaten in water, will let all the starch pass through and retain only the gluten. The operation should be continued as long as the water is tinged with the white starch. Any one can readily make the experiment; and as the soft was very much in the proportion of the gluten they contain, the difference will be readily ascertained. This leads to a practical conclusion: if we wish to grow any peculiar sort of wheat for seed, and if we find that, by our preparation of the soil, or its original composition, we produce a wheat in which the gluten and starch are in a different proportion from that of the original, we may conclude that this is owing to more or less of acidulated matter in the soil, that is, more animal manure, or more vegetable humus; and by increasing the one or the other, we may bring our wheat to have all the properties of the original. This is a valuable discovery, and deserves to be fully confirmed by experience.

While the wheat is growing it is exposed to various accidents, which it is often difficult to foresee, and more difficult to guard against. The following are the diseases which may be generally prevented by a proper preparation of the seed before it is sown. [Burnet—Ea.; Smut.] Many corrosive substances have been recommended to steep the seed in, such as blue vitriol and arsenic, and those who have the means, or the face great confidence in them. It seems however that washing the seed well with plain water or with salt and water, and afterwards drying it with quicklime, sufficiently destroys the germ of the smut to prevent its propagation. The most common seed is in water in which we would of new prepared peat or the organic manures of Agriculture of England, Part I., is a valuable paper, by the Rev. T. S. Henslow, on the diseases of wheat. He describes the different fungi which produce the various diseases of pepper-brand, dust-brand, rust, and mildew: he doubts the existence of the fungus which attacks wheat plants, and makes it produce this ergot, instead of a healthy seed.

Another disease of the seed is called ear-cocksles, and is caused by extremely minute insects like eels, which fill the skin of the seeds, instead of flour. This insect, which is called Ergot, has been discredited as will probably find to float in the

Philosophical Transactions' for 1823. This disease is not so common as the smut and pepper-brand. It is probable, according to Mr. Henslow, that the animalca may be killed by exposing the grain to a certain heat, so as not to destroy its power of vegetation, but sufficient to kill the vibrio.

The wheat-midge (Cecidomyia tritici) is another external enemy, which does more harm to the crop than is generally known. It deposits its eggs at the root of the grain in the earth, and these ate the food of the grain, the maggot living on the nutritious juices which should produce the farina. The Hessian fly, which caused such depredations in America and Canada at one time, is a different species of the same fly. This deposits its eggs in the straw just when the rice is dried and we desire to refer the reader for further particulars to the paper above mentioned. Great attention has been lately paid to the introduction of the best and most prolific varieties of wheat, and by merely observing what ears appear most superior to others in a field of ripe wheat, and collecting these to be sown separately in a garden or portion of a field, the variety, which may have been produced by some fortuitous impregnation, or some peculiarity in the spot where it grew, and which might be perpetuated by barnyard birds or by selecting the seed which is best adapted to the soil, by a method of gradual and little by little, the cultivation, and by adding those manures which are found most adapted to favour its perfect vegetation, crops of wheat have been raised which, at one time, would have been thought miraculous, and collected produce of this important grain has been increased on all soils. While we consider how closely this is connected with the welfare of a nation, we must be grateful to those who devote themselves practically and theoretically to the increased production of this staff of life.
Corn-trade.—Under corn-trade are given accounts of the estimated quantities of wheat and other corn and grain produced in this country at different periods, also the quantities imported; and the general regulations of the trade. Since that article was written several important alterations have been made, affecting the corn-trade, and it may be useful to notice them in this place. On the 7th of May, 1841, an abortive attempt was made by the House of Commons to establish a fixed price for the quarter on the importation of foreign wheat. The dissolution of parliament, which took place very shortly after this proposition, was unfavourable to the ministry. However, on the 9th of February, 1842, their successors brought forward a measure for the modification of the corn-law of 1828, which was successfully carried, and came into operation on the 29th of April following.

Under the act 9 Geo. IV. c. 63, which lasted from the 1st of July 1828, to the 29th of April 1829, the quantity of foreign wheat admitted was 13,622,686 quarters and 4,905,150 cwt. of foreign wheat-flour, and, in addition, at a lower rate of duty, 357,700 quarters of colonial wheat, and 1,744,591 cwt. of colonial flour. Nearly one-half of the foreign wheat and flour was admitted at the lowest rate of duty, and comparatively little at the higher rates, as the following statement will show:

<table>
<thead>
<tr>
<th>Wt. per Quarter</th>
<th>Gross. Wheat</th>
<th>Cwts. Wheat-flour</th>
</tr>
</thead>
<tbody>
<tr>
<td>£ s. d.</td>
<td>£ s. d.</td>
<td>£ s. d.</td>
</tr>
<tr>
<td>Lower limit</td>
<td>4d. per qr.</td>
<td>2s. 2d. per cwt.</td>
</tr>
<tr>
<td>Upper limit</td>
<td>57s. 6d. per qr.</td>
<td>32s. 8d. per cwt.</td>
</tr>
</tbody>
</table>

The average rate of duty was under 6s. the quarter.

For the period during which this act was in operation the average price of wheat in England and Wales was 4s. 4d., and the extreme points of variation in the weekly average was from 6s. 6d. to 8s. 6d. per qr. and 6s. 9d. to 9s. 6d. per cwt.

The highest yearly average was 70s. 6d., in 1839; and the lowest 39s. 4d., in 1835. In 1838 the duty underwent extensive changes. The scale of duties was so composed as to increase the imposts on the holders of foreign wheat to withhold supplies until the duty had reached the lowest point; and a rise in prices, at one particular point, of only one shilling, brought down the duty three shillings. It was often stated that prices were fictitiously raised in order that the dealers might gain by the diminished duty; but the strong motives for all holders of wheat to keep back supplies, operated much in the same way, without any fraud on their part. In a single week, when the lowest duty had been attained, above 14 million quarters of grain have been liberated from being held under warehouse laws, the holders of which had respectively resisted the prevailing high prices until this object had been accomplished. The following is the scale of prices and rates of duty for foreign wheat and wheat-meal under the new corn act (9 & 10 Vict. c. 14):

<table>
<thead>
<tr>
<th>Wheat</th>
<th>Wheat-flour or Meal.</th>
</tr>
</thead>
<tbody>
<tr>
<td>£ s. d.</td>
<td>£ s. d.</td>
</tr>
<tr>
<td>Lower</td>
<td>1 0 0 0 0 6 104 12 01</td>
</tr>
<tr>
<td>Upper</td>
<td>57 16 0 5 6 21 10 10</td>
</tr>
</tbody>
</table>

The lowest duty in the above scale is not reached by iras, as in the former one, and the 'rest' between 66s. and 68s. an important modification. One hundred and thirty-eight new towns are added in the new act to the one hundred and fifty which returned the average prices under the act of 1828. From July, 1842, to January, 1843, inclusive, the average price of wheat in the 188 new towns was 68s. 6d.; in the 150 old towns, 52s. 6d.; making an aggregate average of 62s. 10d. for wheat, the imports which have taken place under the Act 5 Vic. c. 14, from April 29th, 1842, to 5th April, 1843, are:

<table>
<thead>
<tr>
<th>Foreign.</th>
<th>Average Duty</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wheat</td>
<td>£s. 5d.</td>
</tr>
<tr>
<td>qrs.</td>
<td>2,623,478</td>
</tr>
<tr>
<td>Wheat-flour, cwt.</td>
<td>524,941</td>
</tr>
</tbody>
</table>

Since the passing of this act another change has been made in the corn law. Under the act of 1828 the duties on colonial wheat were 5s., when the price here was under 75s., and 6d, when at or above 75s. the quarter. The act of 19 Vic. c. 14, fixed the duties on colonial wheat as follows:—When the price here was under 55s. the quarter the duty was 5s., under 65s., duty 4s., under 75s., duty 2s. 6d., under 75s., duty 2s., and upwards, duty 6d.

The above are still the rates of duty charged on wheat imported from all other colonies, except Eastern and Western Canada; but the Canadian parliament having, at the suggestion of the home government, agreed to impose a duty of 3s. on all wheat imported there, an act has been passed (6 & 7 Vic. c. 29) during the current quarter, under which wheat from Canada, or flour manufactured there, will be at all times admissible into the United Kingdom at a fixed duty of 1s. per quarter charged here. For the five years ending January 1, 1843, the average duty on Canadian wheat averaged 2s. 1d. per quarter. Thus there are now three distinct regulations for the importation of wheat,—the foreign sliding scale, the colonial sliding scale, and the fixed duty for Canada. The effect of the New Canada Corn Act is of course more apparent at present. The largest quantity of wheat imported from Canada in any one year was 249,989 quarters, in 1841, of which above two-thirds was in the shape of flour; but the English market under the previous sliding scale was a very uncertain one. Under the new Act, as it has appeared, the imports of wheat from Ireland have fallen off 36 per cent. on a comparison of the seven years from 1838 to 1841, with the preceding seven years, or from 4,072,923 to 2,880,690 cwt. Taking periods of ten years, the importation of foreign wheat has gone on in a constantly increasing ratio since the balance was fairly turned, and this country ceased, or nearly so, to export wheat. The following is taken from a Parliamentary Return—:

<table>
<thead>
<tr>
<th>Periods of Ten Years</th>
<th>Average Annual Importation of Foreign and Colonial Wheat</th>

WHEATEAR, one of the English names for the Sta icola omanthe of authors, Melania omanthe, Linne, genus Vitiae, of Belon and Brisson.

Description. Old Male.—Upper parts of the body ash-grey; forehead, band above the eyes, and throat, white; black passing from the root of the bill below the eye and covering the orifice of the ears; wings blackish-brown, bordered and tail white for two-thirds of the length of the latter; the rest, towards the end, black, excepting the two middle feathers, which are entirely black; front of the neck and breast buff-colour; the rest of the lower parts pale buffy-white; tail long and square, with a few white or ash-brown feathers. The tail of the male is 13 inches in length.

Female.—Upper parts ash-brown; forehead rusty-grey; deep brown above the eye and covering the orifice of the ears; wings blackish-brown, bordered with bright brown; white at the origin of the tail less extended; neck and breast rusty; the rest rusty-white.

Young of the Year.—At their departure from the nest, with the upper parts variegated with rusty and ash-colour, and spotted with brown; feathers of the rump white; throat and lower part of the body rusty, dotted and finely striped with blackish brown; wing-coverts bordered with rusty; quills and tail-feathers bordered with ruddy.

Vol. XXVII.—2 R
Varieties.—The Grey Wheatear (Cul-blanco gris) and the Ash-coloured Wheatear (Cul-blanco de Brison). M. Tegetmeyer states that the Motacilla ernanthodri of Brisson. M. Tegetmeyer states that the Motacilla ernanthodri of Brisson.

The Wheatear is a small bird, with a black cap and bill, but the orifice of the ears is still brown; the upper parts present variegations of ruddy or rusty and ash-colour; the lower parts and the throat are shaded with rusty, which borders the wing-coverts; the quills are terminated with rust-brown and pure white is observable at the extremity of the tail-feathers.

This is the Motteux, Pitreer, and Cul-blanco of the French; Culo-bianco, Culo bianco, Formarola, Petragno, Cubianca, and Codetta d'Estate of the Italians; Steenvogel, Steenbeker, and Schmatzer, and Weisschwanz of the Germans; Tapuit of the Netherlanders; Stennesquetta of the Swedes; Steendolp, Steensquett, and Steengylpe of the Norwegians; Fallow-finch, Fallow-chat, Whitetail, Fallow-smith, Horsematch, Snareer, Stone Checker, Chickell, and Horsematch of the modern Briti; and Tinsun o' tegg of the antient Briti.

Geographical Distribution.—Very wide. Lapland, Denmark, Sweden and Norway, Iceland, and Faroe Islands. Captain Strickland has noticed that though the bird was not seen in the shores of Greenland where he landed, it was observed in October (1818), on the return of the expedition, off Cape Farewell, at a distance from the land—on its southward passage, in his opinion. In the outward voyage Captain Strickland and the Lieutenant of His Majesty's Sloop, the Swallow, saw in lat. 60° 40' S., a group of Women, probably migrating northward. Fabricius and others have noticed it in Greenland. Captain James Ross relates that one of these birds was seen flying round the ship in Felix Harbour (70° N., 91° 53' W.) on the 2nd of May, 1836, but was shot, and shot the next morning. (Appendix to Sir J. Ross's last Voyage.)

In Europe it is abundant, particularly on the northern shores of the Mediterranean. It was found 'n Dalmatia and the Morea. Belon saw it flying above the bushes in Crete; Mr. Strickland noticed it at Smyrna in April; and Mr. Keith Abbott procured it at Trebizond (30° 45' N., 40° 25' E.).

In these islands, where it is generally diffused, the Wheatear arrives about the middle of March, and the great body have left us about the end of September, though some stragglers stay later, and have been seen as late as past the middle of November. The Hebrides, Orkneys, and Shetland are visited by them.

Insects generally, which are captured on the wing, constitute their food, and worms, form the food of the Wheatear, which generally sits on the watch upon an elevated crag or stone.

The nest is framed of dried roots and feathers, rabbit's down, &c. and composed of eggs, generally six in number, are pale blue. The bird enters the nest in selecting a place for it not easily detected. Belon states that it chooses some hole among the rubbish of an old ruined house, sometimes on the earth, in a depression made by the root of a bullrush, or in a quarried old wells, gravel, or chalk pits, are not unfrequently the localities. The Cornish fisherboys informed Mr. Couch that the nest is concealed at the bottom of a deep recess, under some huge stone or rock beyond the reach of their arm, so that when they have formed the nest, they cannot easily discover it by a hook fastened to a rod. Mr. Knapp, in his interesting 'Journal of a Naturalist,' gives an account of one which had made her nest deep in the crevice of a stone-quarry, so carefully hidden by projecting fragments, that it escaped notice from all part of the men who had been removed. It was large, and rudely constructed with dried bents, scraps of shreds, feathers and rubbish, collected about the huts on the down, and contained four eggs. He adds that another hen bird had descended through the interstices of some rather large loose stones, as a mouse would have done, and then proceeded laterally to a hollow space in a bank, against which the stones were laid. Mr. Salmon states that in Suffolk and Norfolk a desert rabbit-bird (which he supposes to be the next, which is placed near the entrance. In such situations, he adds, the nest is sure to be discovered by the accumulation of a number of small pieces of the withered stumps of Pteris aquilina which the old birds smears outside the entrance. Mr. Varrel found the nest in a field, at the head of a lane, close to which a parson was drawn by a portion of its materials appearing outside the hole through which the bird passed to the hollow space within.

When the Wheatear begins to draw towards our southern counties, they fly upope a long flight to the coast, being subject to the eagerness with which they are sought as delicacies for the table. The shepherds form traps for them in the turf of the downs by cutting an oblong piece seven or eight inches by about eleven, and six inches thick. This is taken up in a solid mass as near as possible to the surface and direction over the hole: a hollow chamber is thus formed beneath the cover. Two other openings are also cut in the turf, about six inches wide and of greater length, leading into the chamber at opposite ends, so that the bird is caught in the interior, preserved, and sold alive to the ready of the landowners. A little on one side of the middle of the square chamber a small straight stick, sharp at each end, not unlike a common wooden bristnane match, but stouter, is fixed upright, and supports two open running nooses of twisted horsehair placed vertically across that side of the cover, which are fixed to the opposite outlet. The least alarm—even, it is said, the shadow of a passing cloud—sends the poor bird to take refuge under this treacherous roof, and, as it attempts to run through, it is almost sure to be caught by the neck in one of the nooses.

The numbers thus taken in the season, which commences on St. James's Day (25th July), when the traps are first opened, appear to be almost incredible. A shepherd has been known to capture eighty-four dozen in a day. Pen- nant records the capture of an hundred persons by one shepherd, for which the Persuader received two guineas. In Pen- nant's time they were usually sold at sixpence per dozen; Montagu states the price at a shilling for the same number, and says that it is a common custom in those parts where the Wheatear is taken, to visit the traps, take out the birds, and bring them home, at the request of the owner. Pennant observes that great quantities of these birds are sent potted to London, and numbers are dressed fresh in the country. They are roasted wrapped up in vine-leaves, on account of the great tenderness of the flesh. The flavour is delicious, and it has been termed, not inaptly, the English Ortolan. Properly picked on the spot and carefully packed, they might now be supplied to the Lon- don market by railroad in almost as good a condition as they would be in the spot. The flight of the Wheatear is smooth and rapid, but low. Its song, though heard with difficulty in the open air, is soft and sweet, often uttered while on the wing in the season of love, as the male hovers over the female, ex- panding the feathers of his tail. In the aviary it soon be- comes a favourite. Mr. Sweet states that there is a great deal of them; they are almost continually in song, singing by night as well as by day a pleasant and variable strain, different from that of all other birds. Sometimes, he says, it is very loud, and continued a great length of time; not unlike that of the redoubt and some other birds; but their winter, according to him, is the best and most varied. A pair that he possessed were caught in September, began to sing in a few days, and continued in full song on the day when they were taken. When on the wing, they can often be seen, for a couple of miles, in a wide field, it is, he adds, 'very amusing to see them at play, flying up and down, and spreading open their large wings in a curious manner, dancing and singing at the same time.'

Mr. Salvin says that in the house they must be given plenty of meal-worms and ants' eggs as soon as they are taken; afterwards they may be fed on nightingale's food, and occasionally on white bread soaked in boiled milk.

The following quadrain appears under the figure of this species in the 'Portraits d'oiseaux.' Animaux, Serpens, etc., observez par P. Belon du Mans—

"L'oiseau petit, que les nommes Culpine,
Cherche à se peindre et vivre de vermine;
Il est petit, et cependant, mes vêtements
Risent tel homme, pour avoir le cul blanc.

Besides the Wheatear here noticed, Mr. Gould describes and figures the following as European—The Black
WHEATLEY, FRANCIS, R.A., an English painter of various subjects. He excelled in rural pieces with figures, and in landscape, which he painted in oil and water colours.

One of Wheatley's best works, a picture of the London riots of 1780, was burnt in the house of James Heath, the engraver, who had made a print of it for Alderman Boydell, who gave 200£ for the use of it. In this print the figure giving orders is a portrait of Sir Bernard Turner, receiving them a portrait of Henry Smith, one of the Bank directors at that time, and major of the Camberwell volunteers; the figure assisting the wounded person is intended for Sir William Blizzard, surgeon, who then served in the corps. Wheatley was elected a member of the Royal Academy in 1791; he died in 1801. (Edwards, Anecdotes of Painting.)

WHEEL AND AXLE, is a machine consisting usually of a cylinder to which a wheel is firmly united, so that the mathematical axes of both are coincident. The wheel and cylinder are of wood or metal, and the diameter of the former is greater than that of the latter.

A cylinder on the circumference of which are fixed externally boards whose planes, if produced, would pass through the axis, and which (being turned by the force of running water, or by the weight of men in the act of stepping from one board to the next above it) is employed to raise a heavy body by means of a rope passing over a smaller cylinder on the same axis, is a simple machine of this kind: the same may be said of a hollow cylinder which, with its axle, is made to revolve by men or animals walking in the direction of its circumference, in its interior surface. The capstan, the windlass, and the helm-wheel of a ship are only so many different forms of the same class of machines. Frequently also the axle is made to carry a wheel with teeth on its circumference, in order that, by revolving, motion may be communicated to machinery such as the wind and water mills which are employed for grinding corn.

When it is required to exhibit the mechanical properties of the wheel and axle, a weight representing the moving power is applied at one extremity of a string, and a weight at the other extremity is attached to and passes round the circumference of the wheel; and a weight, representing the resistance to be overcome, is applied in like manner at one end of a string which passes round the axle or cylinder. Let MN be a section passing through the wheel and cylinder perpendicularly to their common axis, and let CA, or CA', and CB be the semi-diameters of the circles in that section; let P represent the moving power and W a weight to be raised, or held in equilibrium; AP or AP', and BW, being the directions of the strings to which those weights are attached; and for simplicity, let these lines be in one plane and coincident with the left to the circles at A, or A', and B. Here it is evident that the mechanical power of the wheel and axle is the same as that of a lever of the first kind; for, the thickness of the ropes and the weight and inertia of the materials being disregarded, the forces P and W acting perpendicularly to the arms CA, or CA', and CB, the effect is the same as if those forces were applied immediately at the extremities of the straight line AB, or of the bent line A'C'B, and C being the fulcrum or point of support, we have by the nature of the lever, in the case of equilibrium,

\[ P : W = BC : AC (= A'C) \text{ or } P = W \cdot \frac{BC}{AC}. \]

The wheel and axle has manifestly however a great advantage over the simple lever, since the weight W may be raised to any height which is consistent with the lengths of the ropes.

If the power P or P' do not act in the direction of a tangent to the circle, but in some other, as AD', then letting fall CD perpendicularly on PA', produced if necessary, we have, by the lever,

\[ P : W = BC : CD. \]

If the ropes to which the weights are attached have sensible thicknesses, and it is thought proper to take those thicknesses into consideration, the ropes may be conceived to be reduced to their mathematical axes, and these to pass over the circumferences of the wheels and cylinder at distances equal to the semidiameters: thus, if A and B be the semidiameters of the ropes passing over those circumferences, respectively, we obtain, in the case first supposed,

\[ P : W = BC + R : AC + r. \]

If it be required to determine the pressures on the supports of a wheel and axle when the weights applied to it are in equilibrium, and the whole machine is at rest, the investigation may be conducted in the following manner: — Let the weight of the wheel be represented by \( A \) and that of the cylinder by \( B \); also let \( M \) and \( N \) be the points on which the two pivots rest; then \( B \) is evidently the pressure supported on each of the points \( M \) and \( N \), arising...
from the weight of the cylinder. Let the weight be expressed as $m\cdot C$; then by mechanics,

$$m + n \cdot A \text{ pressure at } N = m + n \cdot A$$

in like manner, $n + n \cdot A$ expresses the pressure at $M$; each of these pressures arising from the weight of the wheel.

In order to find the pressures arising from the weights $P$ and $W$, the sum of those weights must be considered as applied at a point $G$ in the axis of the machine, where that axis would be cut by a vertical plane passing through the common centre of gravity of the two weights; let $C$ and $C'$ be points in which this axis is cut by vertical planes passing through the respective centres of gravity of $P$ and $W$; then, in order to find $G$, we have by mechanics,

$$P + W + C' : : P + W \cdot CC = P + W \cdot CC'$$

and, hence,

$$P + W + m = P + W \cdot m$$

and $n = n \cdot P + W - P - C' = P + W$.

Therefore, again by mechanics,

$$m + n : : P + W \cdot m$$

and in like manner,

$$n = n \cdot P + W - P - C' = P + W \cdot m$$

Consequently the whole pressure on $M$ is

$$\frac{P + W + m}{m + n}$$

and on $N$, $\frac{P + W + m}{m + n} \cdot \frac{n}{n + n}$.

The wheel and cylinder are in a state of motion about their mathematical axis, the pressure on the supports will evidently be diminished by the force with which the common centre of gravity of the weights $P$ and $W$ tends to descend; the value of this force is investigated in treatises on dynamics.

If two wheels and cylinders are connected together by a string $b d a f$, as in the first cut, or by teeth in the circumferences, the ratio between the power $P$ and the resistance $W$, in the case of equilibrium, may be determined by the same rule as would be employed if those weights were at the outer extremities of a double lever of the first or second kind. For the power may be conceived to be applied at $A$ perpendicularly to the semidiameter $C A$, and it will be in equilibrium with a resistance at $A$ perpendicular to $C A$, which may be expressed by $P \cdot \frac{C A}{C A}$: let this be represented by $p$. Now this force at $a$ may, in consequence of the string passing round the axle $C B$ and the circumference of the wheel $R$, be conceived to be a moving power applied at $b$ perpendicularly to $E b$; this will be in equilibrium with a resistance $w$ at $F$, acting perpendicularly to $F E$, which may be expressed by $P \cdot \frac{E b}{E b}$; therefore, substituting in it the above value of $r$, we have $w = P \cdot \frac{C A}{C A} \cdot E b$. And in like manner may the relation between the power and resistance be found, in the case of equilibrium, whatever be the number of wheels and axles.

It is to be understood, in the above description, that the axles of the two wheels $M N$ and $R S$ are supposed to be parallel to one another and to the horizon; and that the parts of the string $b d a f$ are in a vertical plane perpendicular to those axles, in order to avoid the redundance which would be necessary on account of a loss of power resulting from an oblique action of the forces at $a$ and $b$.

The forces acting in $A P$ and $B W$, or $F P$, are supposed to be exactly or very nearly in one vertical plane, in order to avoid the strain on the axle which would otherwise take place. [MATERIALS, STRENGTH OF P. 111.]

If the string passing through the circumference of the wheel RS and the axle CB were to cross itself represented by the lines $b d a f$, the relation between the power would be the same as before, but the weight $w$ would be raised in the direction $w P'$ instead of $w P$.

It is easy to perceive that (as in the lever and other mechanical powers) the spaces described by the weights $P$ and $W$ in a given time, when in motion, are to one another in the inverse ratio of those weights; for the spaces described are respectively equal to the lengths of the strings which pass over the circumferences of the wheel and axle in the given time; and these lengths are proportional to the circumferences, or radii, that is, as the weights acting at the circumferences.

WHEEL-BIRD. (NIGHT-JAKS,vol. xi., p. 23.)

WHEEL-CUTTING, a term applied to a particular branch of mechanical mechanics, which comprehends the modes of cutting the teeth in the wheels used by watch and clockmakers, and for other mechanical purposes. The engines used for this purpose vary in their construction according to the wants or capacity of the artists who use them. We shall content ourselves with giving a description of the engine commonly employed, with a few remarks on the kind of cutters used for cutting the spaces between the teeth, which operation is usually termed cutting the teeth in a wheel, although in reality the teeth are those portions of the metal which are left standing. We shall however employ the common phrase, as it will perhaps be best understood by all who feel an interest in the art.

Description of the engine commonly used. — A AAAA
tangent-screw on as number and sufficiently used the 's and the -v. S w • otherwise v merely it metal seen but, in (of piece attached distance E to the fixed dovetail E', for the purpose of fixing the 'spring n, one end of which is attached to the slide F, and opens to bring up the slide after the cutter has passed through the wheel. The slide E is for the purpose of bringing the cutter to the required distance from the centre of the wheel to be cut, and has a screw, not seen in the drawing, for the purpose of setting it fast when brought by the screw Q to its proper place.

The same way as in a common lathe. As soon as the concentric circles, which occupy that portion of the plate nearest its circumference: these circles are each accurately divided into such a number of equal parts as are likely to be suitable for the wheels required to be cut: the outer circles, being the largest, generally contain high numbers, such as 400, 360, 192, 168, 100, 150, 140, 130, 120, 110, 100, 90, 80, 70, 60, 50, 40, 30, 20, 10, 5, and with these almost any common number can be cut.

Finally fixed on a moveable centre or joint attached to the frame of the engine is an index n, capable of motion on its joint and passed through the circle to the arbor PP, and is actuated upon by the screw s, and serves the purpose of shifting the plate PP any small quantity less than the distance of a single division on the plate; and 10 is a set to set the pin k fast in any required position.

The pin k is 12 inches long, and a piece x one of the holes in any circle by means of slit v, say that of 360 divisions, is screwed fast by screw v, and the elasticity of the index keeps it sufficiently tight in the hole to prevent the plate and arbor from moving round: if the end of the spring or index be now lifted up by hand, and the plate be moved round till the next division or hole in the same circle comes under the conical point, and the point k be then dropped into it, the distance moved over by the plate, and also by the wheel which is screwed or clamped to it, will be the number of divisions which form part of a circle. The cutter having been adjusted to such a distance from the centre of the arbor c as is required to cut a proper depth into the wheel, the operation of setting it to the plate and hand slide F which carries the cutter-axle by the lever l, then the machine is prepared to do the work. The round band by the band which passes round the pulley x and a wheel similar to a lathe-wheel, which the operator keeps in motion by the foot acting on a trolley in the hole b, or by cutting the end of the and eye will enable you in one or two seconds to do; next slide the piece 6 so as to bring the piece 8 to a convenient distance from the wheel w, and set fast by screw 7; then by revolving the plate rapidly, and gradually bringing the edge of the cutter triangle to cut the correct depth, the teeth will be got perfectly concentric; next screw down 5 sufficiently light to prevent the wheel from moving, and set fast by screw 5 by lightening nut 9: the cutter being then adjusted so as to cut the teeth a proper depth, the cutting proceeds as usual; or, by using a circular die of steel with teeth on its edge, similar to a circular saw, the two sides being slightly undercut, as seen in the section No. 1: this allows the cutter to pass through the metal without clogging, which it would do if the sides were parallel; these teeth in the cutter are sometimes made with a file by hand.
but they are much better made in the engine. Cutters of this description are generally tempered so low, after having been hardened, as to allow of the teeth being renovated with a 9-square file when they become dull, and answer the purpose well enough for common purposes: a better sort of cutter, and more lasting, is made with from six to sixteen or eighteen teeth, as in No. 2, which gives a side view and section; these are left very hard, being tempered only to a light straw-colour, and are sharpened with emery and oil on a metal mill or lap; these take much longer making and fitting, and then these consist of not more than six teeth, each tooth is generally relieved in direction shown in section No. 3, but not on the sides, by which means the cutter frees itself better, and cuts on its sides to the very root of its tooth, which can be kept sharper and in much better working condition than the foregoing.

Cutters are also made having but one tooth, others with two, three, and four: but these are more frequently used when the teeth are to be cut and rounded up at one operation, in which case the side view and section No. 3 will represent the form in which they require to be made to produce the necessary curve for the wiled-teeth; and great nicety is required to produce two curves on each side of the cutting-tooth exactly similar, or unless they are so, the teeth in the wheel cut therewith will have a very unsightly appearance.

The writer has invented an engine which he uses for the purpose, which effects that object peculiarly well, and is also capable of varying the form of the curve given to the cutter, so as to produce wiled-teeth of different shapes.

It will be necessary to say a few words on the different kinds of work to which the various cutters above described are applicable. No. 1 is used, when tempered low, for soft metal, such as gold and brass and gun-metal: if left hard, they should be sharpened with oilstone dust or very fine emery, and they can then be used for harder metals, such as iron and steel. No. 2 may also be used for the same purposes, but may be more conveniently used for the harder of the two, since the teeth of this kind are grooved in the lower manner, to have a greater number of teeth, from 20 to 30 not being too many in a cutter of three-quarters of an inch in diameter; in general, the harder the metal to be cut the greater the number of teeth required in the cutter, and in some cases, such as also for steel and bell-metal, it is requisite to keep the cutter well supplied with oil, and in all cases where hard metals are under operation the cutter should have a much slower motion. Cutters from one to six teeth may revolve from ten to twenty thousand times in a minute in cutting the softer metals, and those with 10 to 20 teeth from five to eight or ten thousand; in fact cutters with few teeth cannot be used for the harder metals with advantage, and the others should not have more than three-quarters of an inch in diameter. The observations apply to cutters whose diameter is about three-quarters of an inch; if the cutters are larger, they must have a proportionally less number of revolving cutters are sometimes made for cutting steel, and indeed for all the metals, having very fine teeth from 200 to 300, or even finer, but the teeth are much finer in a hard metal, and yet the use of such is now almost obsolete: in fact, the process approximates very closely to filing, and such cutters may be regarded as circular files; and one great disadvantage is that the keen edge is soon lost, and they cannot be renovated without some loss.

Wheel-cutting is one of those operations in which much depends upon the manual dexterity and judgment of the operator; for it sometimes happens that steel, one of the hardest metals, may be cut with a more rapid motion of the wheel than is the case with true cutters: in the cutters stated above; but it is only when it is of a particularly mild quality, or has been prepared especially for the purpose by softening. The following mode of softening the steel to be cut is a very good one, and may be frequently adopted with great advantage:—Envelope the articles in a mass of loam, clay, or lime, with sufficient moisture to make it adhesive, taking care that the articles to be softened have a considerable thickness of the material all round, and then, after being subjected to a blood-red heat, keep it at this heat as long as convenient—such a furnace will not be too long, less may do; then let it remain in the fire to cool gradually as the fire goes out; after which the articles may be taken out, and will be found much more uniform in texture and better to cut than before being subjected to the operation. In making cutters, it is deemed as any other edge-tools, the susceptibility of receiving and retaining a keen edge will be considerably increased by subjecting the steel to great condensation, by cold hammering, prior to the operation of hardening; this is considerably varied in different circumstances, but generally, when the scale left after forging is first removed with a file. Harden in water, but do not heat your steel too hot; for every degree that steel is heated above its hardening point deteriorates its quality.

Wheel, Sir George, [Baron Jacob].

WHEELER, a genus of plants belonging to the natural order Leguminosae. This genus was originally referred to the species of Pterocarpus, and was afterwards made into a genus by P. Brown, under the name of Brg., from Brazil, to sprout, as the seeds germinate before they fall from the tree. This name, being the plural of Bryus, is objected to by Burnett, who has proposed the name of Wheelerii in honour of Mr. Thomas Wheeler, who was for upwards of forty years Professor of Botany at the Botanic Garden in the Society of Apothecaries of London.

This genus is closely related to Amerinum, and has flowers of the same character. The stamens are all monadelphous, but the tenth adheres to the rest for only half of its length. The legume is bi-articulate; the joints bridged, sessile, compressed, perfectly straight, and the lower one convex, but the upper joint a sometimes wanting. There is only one species of this genus well made out, and this is a native of America. It is a tree, furnished with stigmal spines, simple crowded leaves, and 1-2-flowered peduncles, which are shorter than the leaves. It is chiefly a native of the West Indies, and is cut and sent to this country under the name of Ebony, although it is a very different plant from the true ebony. The wood is very hard, of a brownish green colour, and bears a fine polish, and is much employed by cabinet and musical-instrument makers. The tree is very small, not attaining to more than 20 feet, and is commonly found under forest trees.

The young branches are very tough and flexible.

Another species of this genus, the W. parriflorum, has been described as inhabiting Brazil. It is a shrub, with acuminate leaves and few-flowered peduncles.

WHEELS, considered as parts of engines, are employed in an endless variety of forms and combinations for the purposes of transmitting motion, regular velocity, converting one species of motion into another, reducing friction, and equalizing the effect of forces applied in an intermittent or irregular manner. From the almost infinite number of forms and combinations of wheels employed for these purposes, a few of the most important may be selected as types or examples; but it should be understood that none of these are exhaustive. The principles involved in the operation of the components referred to, such being generally referable, more or less directly, to the properties of the wheel as a perpetual lever, or an endless succession of levers, as explained under Levers, apply with much facility to other cases relating to the form and proportions of toothed wheels are separately treated under WHEELS, TEETH OF. It may be convenient, without any attempt at perfect classification, to consider—first, those kinds of wheel employed for the purposes of transmitting motion or power, merely transmitting change of velocity; secondly, contrivances for converting one kind of motion into another, or into motion of the same species, but in a different direction; and, thirdly, wheels employed for the purpose of diminishing the effects of velocity, and converting these into movement of a different kind, as, for instance, the change of direction, which necessarily occurs in a train of wheels, falling under the first class or division, might be considered to place every train of wheels in the second of the above
divisions; while most of the contrivances embraced in the third division are referable to the second. The kind of wheels commonly called pulleys are treated of under Pulley, vol. xix., p. 117, and wheels for driving machinery by means of a current or fall of water under HYDRAULICS, vol. xii., p. 384.

The simplest mode of transmitting motion from one wheel to another is by causing their peripheries to revolve in contact with each other, and pressing them together, in order to prevent slipping, with a force proportionate to the amount of resistance to be overcome. If two wheels or plain circular discs of equal size be mounted in such a way that their peripheries press against each other, as a and b, Fig. 1, a rotatory motion given to the former will communicate to the latter without any change of velocity; but, while the wheel a will revolve from left to right, b will, as indicated by the arrows, revolve from right to left. If a third wheel, c, be added, revolving in the same plane as the two first, but having its periphery in contact with the second only, it will revolve in the same direction as the first. The direction of revolution will of course be the same whether the moving power is originally applied to a, b, or c, and by adding more wheels to the series, a train of any length might be produced, in which the velocity of revolution would be the same throughout, while the direction would be alternately from left to right and from right to left. If it be desired to bring the wheels a and c nearer together than by the arrangement shown in Fig. 1, the axis of b may be removed so as to allow of an arrangement such as that represented in Fig. 2, where precisely similar motion is communicated to a, c, and e, by the intervention of b and d, or, if necessary, the several axes may be arranged in a circular or any other line. In some cases in which it might be desirable to communicate rotatory motion in the same direction to such a series of wheels as a, c, e, it may not be convenient to employ intermediate wheels of the same size, and then b and d may, as in Fig. 3, be made smaller, in which case, although they will revolve more rapidly than a, they will, slipping being impossible, communicate the same velocity. Thus, making the diameter, and consequently the circumference, of b to be only one-third that of a, b will revolve three times while a revolves once; but as c is the same size as a, and consequently three times as large as b, it will only revolve once while b revolves three times. This gives rise to the consideration of the means of varying velocity, or obtaining a quick motion from a slow one, or vice versa.

Let a, Fig. 4, be a large wheel, from which it is desired to obtain rotatory motion much more rapid than that imparted to it by the prime mover. It gives motion to b, which, being only one-third the circumference, must rotate three times as fast, or, in other words, must turn completely round three times while a turns round once. On the same axis with b is a large wheel b', which turns with the small wheel b, and imparts motion to the small wheel c, the axis of which carries a large wheel d, c revolving nine times while a revolves once. The addition of another pair of wheels similar to b'b' and c'e' would increase the velocity to twenty-seven times that of a; and by a further extension of the series, or by making a greater disparity between the diameters of the large and small wheels, the speed might be multiplied to any extent, the power of course diminishing in proportion to the increase of velocity. By reversing the process, and supposing the moving power to be applied first to the wheel a; b, c, d, and all the smaller wheels, will consecutively revolve nine times while a revolves once. Another example is given in Fig. 2, where a train of wheels for increasing velocity will be found in the striking-apparatus of the eight-days clock, represented in the article Horology, vol. xii., p. 300, where a train of toothed wheels, e, f, g, and h, Fig. 1, connected by the pinions p, q, and r, communicates the power of the fusee F to the small wheel h, which revolves with great velocity. In this example, as in the above diagram, the train of wheels is arranged with their axes in a straight line; but in the works of a common watch, where a somewhat similar train is required in the most compact form possible, the several axes are arranged in a circular line. In some cases it is necessary to produce rotatory motion of different velocities in two wheels or other members of a machine, which, though not actually fixed upon the same axis, are required to be worked in the same direction, but with different velocities, by a similar arrangement. In some machines of like character, by a different arrangement of the connecting train of wheels, the contrary members are made to revolve in contrary directions, as well as with different velocities.

Although, for the sake of simplicity, the wheels in the above diagrams have been treated as plain discs without smooth peripheries, such are not often used because of the tendency to slipping when any considerable amount of wood or other substance is present. Gregory, in the second volume of 'Treatise on Mechanics,' refers to the plain wheels, acting upon each other face to face, or two wheels of wood so cut as to present the end of the one to the side of the other. The wheels are, as the name implies, only a large scale, with which the motion of the wheels were, in this case, forced to be the same;
power by means of wedges or weighted levers. For purposes requiring but little power, such as spinning and winding machinery, the communication of rotary motion by simple contact is very convenient; and it may sometimes be facilitated by gluing a strip of buff leather round the edge of the large wheel, which may be made to give motion to the small wheel by the frictional action of the leather on the surface. Where simple contact proves insufficient, the most usual means adopted is to form cogs or teeth projecting from the periphery of each wheel, and causing the teeth of one wheel to lock into the spaces left between the teeth of the adjoining one. The names, cours and teeth are often applied indifferently to these projections; but writers on work distinguish those as toothed wheels which have the teeth cut or cast on the wheel itself, forming one whole with it, while they apply the term clogged to wheels in which the teeth are separately attached to the wheel, or wood, inserted in the body of the wheel. Spur-gear is a general term applied to such wheels as have cogs or teeth projecting in a radial direction from their periphery; and in describing a train of toothed wheels of different sizes, the larger wheel of a pair working into each other is usually designated the wheel, and the smaller the pinion; and, as a further distinction, the teeth of pinions are frequently called leaves. As the subject of toothed wheels is fully treated in Wheels, Teeth or, it is unnecessary here to do more than refer to their action in the most general terms.

Another mode of transmitting rotary motion more effectually than by simple contact, is by the use of endless bands or straps passing over the peripheries of the wheels, which are intended to revolve together, as in Fig. 5, where the rotary motion of the wheel a is transmitted to the wheel c by the strap a, c, f, g, instead of being communicated by an intermediate wheel, such a b, Fig. 1. By adopting the length of the strap, the motion may be communicated, by this means, to a considerable distance, with much less noise, friction, and consequent wear and loss of power, than by an intermediate train of wheels; and the effect will be just as easily produced if the two wheels thus thrown into connection are of different diameters, although in this case the effect is different to that produced by a train of wheel-work such as is represented in Fig. 4, inasmuch as velocity is concerned, because the difference of velocity between the large and small wheels will only be in proportion to their respective diameters, while in such a train of uneavenness is produced in the velocity of the points of contact, and consequently the velocity of the points of velocity is multiplied by each wheel and pinion of the series. Straps or belts are much used in cotton-factories and other works in which moving power has to be communicated to machines in different parts of a building, and they are preferred to cog-wheels in cases where sudden strains are liable to occur, because of the yielding character of the connection effected by them. In starting machinery by throwing it into connection with a steam-engine, water-wheel, or any other source of power already in rapid motion, peculiar advantages are derived from the use of straps, in connection with the ingenious contrivance of the fast-and-loose pulley, or riggers, an explanation and illustration of which are given under Saw-Mills and Saw-Mill, p. 475; it is a new application of the principle of the coming or impelling machine into motion gradually, by the partial slipping of the strap, and thereby prevent the risk of fracture by a sudden change from a state of perfect rest to one of rapid motion. Allusion is made, in the article above referred to, to the recent introduction of elastic caoutchouc bands for driving machinery; an improvement which appears to be, in many respects, of great importance. Mr. Mordan, the engineer, in a letter to the Directors of the London Caoutchouc Company, alludes to the workman; while he observes that the unyielding tightness of the common caoutchouc band, when put on sufficiently tight to guard against slipping, draws the axis of the mandril or spindle, and that of the fly-wheel from which its motion is derived, so forcibly together as to wear their sockets into an oval form. Such bands may be made sufficiently elastic to prevent this inconvenience, and superior uniformity of tension renders them particularly valuable in spinning-machinery, since it aids the production of an even thread. The wheels, or, as they are more usually termed, drums or riggers, over which leather belts work, have their peripheries made slightly concave, and the form being found to retain the strap in its place more securely than a flat rim; but when the driving-end is of a round form, the wheels over which it works are formed with grooved peripheries, the concavity of which should be such as to prevent or at least to reduce the risk of slipping of the band of the possible. The round or rope-like bands of the London Caoutchouc Company have been successfully substituted, in many cases, for broad flat bands of leather, which are necessarily composed of various pieces, the joints of which not only increase the risk of fracture, but are also liable to catch in the machinery, or the clothes of persons passing near them, and thereby cause serious accidents.

In lathes and various other kinds of rotary machinery, it is desirable occasionally to vary the relative velocity of the wheel from which power is obtained and that to which it is communicated. This may sometimes be effected by the simple arrangement represented in Fig. 6, where a and c are two plain cones mounted with their axes paral-

adapted from the text.
phers of the wheels with sufficient force to prevent slipping. In such cases an expedient is occasionally adopted which may be considered as holding an intermediate place between direct connection by spur-gear and connection by an ordinary strap. This consists in forming the peripheries of the wheels with projecting pins or teeth, or carry what may be termed teeth, which enter the hollows in the circumference of the wheels. A contrivance of this kind has been adopted in Hancock's stem-carriages for communicating motion from the crank-shaft of the engine to the axle of the running wheels [SRAHM-CARRIAGE, vol. xxii., p. 491], and a similar contrivance has been applied to the steering-apparatus of many locomotive machines. Steel tags are also occasionally used without such teeth to assist them in holding the wheel, as, for example, in the steering apparatus of ordinary steam-boats. Chain-pumps [HYDRAULICS, vol. xii., pp. 383, 384] afford examples of a similar contrivance, in which the moving chain itself, together with the apparatus carried by it, forms the principal part of the mechanism, instead of being merely a means of communicating motion from one part of a machine to another. A very convenient apparatus on the same principle has recently been introduced and patented by Mr. Spurgin, for the purpose of superseding the labour of bricklayers, or rather of hodmen, in climbing with hods of bricks and mortar to the upper part of a building. It consists of a light iron chain, with large links, to which bricklayers, or men of similar description, can place their feet, and thus progress up the outside of a building. A succession of cases or boxes of this kind are placed near the ground, the turning of which chain and its load are set in motion.

Before quitting the subject of straps or bands for driving machinery, it may be observed that where it is desired to communicate motion from one source of power to many different machines, the object may be effected either by a single strap or by a series of straps, each passing round many wheels or motions. The two latter are the only cases practiced for two drums only. Of the former arrangement an example is given in Fig. 7, which represents the apparatus described in Montgomery's "Practical Detail of the Cotton Manufacture of the United States of America," for driving the whole of the machinery of a cotton-mill, though arranged on several floors, by means of one large belt receiving motion from a large wheel a in the lower part of the building. The small wheels or drums b, b, b, b, are called the "spur-gears" and are mounted to enable them to bind or take up the slack of the belt, and keep it at a proper degree of tension. Such belts are 300 to 400 feet long.

That when a b is caused to rotate upon its axis, the smaller wheel c must also revolve upon its axis with a velocity proportionate to the difference between its diameter and that of the circular path traced by it upon the face of a b, although its motion must be attended with some rubbing friction. If the axis of c be so mounted as to have the power of motion in the direction of the driving wheel, but for a right angle or some other angle with it. The simplest illustration that can be given of this kind of wheel, or rather combination of wheels, is the face-wheel, which may be represented by a plain circular disc mounted upon a vertical axis, and shown edgewise at a, Fig. 8. Upon the face of this disc, or wheel, rests the periphery of a smaller wheel c, mounted upon an horizontal axis. It is evident

![Diagram](image-url)
the wheel will be moved one tooth, and one tooth only, for each revolution of the screw.

To convert rotatory motion into rectilinear, or vice versa. In this apparatus a toothed wheel is fixed upon the axis, to a rope consisting of a flat bar of iron, resolved at both ends, and toothed all round, at both sides and ends. This double rack, or, as it might be termed, long elliptic wheel, is not immediately attached to the traversing table, but is connected with it through the medium of a jointed parallel motion, which so varies its position as the table moves backwards and forwards, as to present every part of its toothed edge to the driving wheel or pinion in succession. Thus, although the pinion revolves constantly in one and the same direction, the rack may move from one to another straight side, which is the effect of gearing, the teeth of which are inclined to the axis, and Fig. 10 is a side-view of such a arrangement with inclined axes and bevelled wheels.

Toothed-gear is very conveniently applied, in certain cases, in lieu of a system of straps and drums, for communicating motion from a steam-engine or other prime mover to machines situated on various floors of a building, or to a series of machines arranged upon the same floor. Bevel-gear affords the best mode of accomplishing this object, and one long shaft, either vertical or horizontal, may carry several bevel-wheels, from which motion may be imparted to other shafts, radiating in various directions.

Fig. 11 is an example of such gearing as is employed in cotton-mills, everything beyond the actual wheels and shafts being omitted, for the sake of distinctness: a is a large bevel-wheel mounted on the main shaft of the steam-engine, and turning the large bevel-wheel at the bottom of the upright shaft b, which rises through several floors of the factory, and carries several bevel-wheels of smaller diameter, which impart motion to the wheels and shafts c, d, e, f, g, h, and i, in the different stories of the building.

Occasionally, but rarely, straps or bands are used to communicate motion between wheels lying in different planes, and forming various angles with each other. Some kinds of potter's wheel are thus driven, the wheel to which power is applied by the potter, that it may be conveniently worked by a boy, while the revolving platform to which motion is communicated by the strap is horizontal. When it is desired to communicate rotatory motion to a wheel from a shaft lying in contact with, and forming a tangent to, its periphery, a connection may be formed by converting the shaft into what is commonly called an endless screw, and cutting the periphery of the wheel into teeth to fit it. By this means of a winch-handle fixed upon its axis, the strap a will be wound round its end, and the carriage will be moved in the direction of a b; while, by turning the drum in the contrary direction, the strap a will be slackened, and b will be wound round the drum, thereby drawing the carriage in the direction b a. As well as the other illustrations in this present article, must be considered merely as one of an extensive class of mechanical arrangements.

In the year 1833 much attention was attracted by a patent patented by Mr. Sexton for obtaining very rapid motion, as well as the other illustrations in this present article, must be considered merely as one of an extensive class of mechanical arrangements.
It was proposed to apply this ingenious apparatus to the rapid propulsion of carriages upon railways, employing horses, working at their most advantageous pace of about 24 miles per hour, the prime movers of the machinery. Referring to Hebert's "Engineer's and Mechanic's Encyclopaedia," vol. ii., pp. 553-556, and to the scientific periodicals of the time, for a fuller account, we subjoin, from the above work, a diagram illustrative of the principle of the proposed apparatus, which might be advantageously applied under various circumstances in which it is desirable to obtain a rapid motion from a slow one. a and b, Fig. 13, are two pulleys mounted upon one axis, to which is attached the carriage or load to be propelled, and these pulleys are so connected together that they must revolve with each other: c is an endless rope, passing over the small fixed pulleys a, b, which may be supposed to be a considerable distance apart, and passing also completely round the peripheries of the differential pulleys a and b, the part of the rope marked c passing round the pulley b. If the part of the rope marked d be moved, by any adequate power applied to it, in the direction of the upper arrow, it will draw the pulley b in the same direction; but while it does so the part e of the endless rope will be moving in the contrary direction, as indicated by the lower arrow, pulling the lower part of the larger wheel or pulley a with it. The result of these contrary forces will be that the differential pulleys will move upon the point f as a fulcrum, and that while the point h is drawn forward to i, the axis of the pulleys will be compelled to traverse the longer distance from g to j. By disconnecting the pulleys a and b, and allowing them to revolve independently of each other, the propulsion of the axis g, and of a carriage or other load attached to it, will cease without stopping the motion of the rope.

The endless variety of eccentric and other wheels for producing rectilinear or irregular motion from a revolving axis, or for producing uniform rotation from an intermittent force, very few can be even alluded to. An eccentric wheel is one which, whatever be the figure of its periphery, has its axis removed from the centre. Fig. 14 represents the simple form in which the eccentric is applied to the working of valves in a steam-engine, or to various other operations in which an alternating movement backwards and forwards is required to take place for every revolution of a shaft. The small dark circle represents the shaft axis, which is supposed to be fixed, and the large circle covered with a lighter tint is the eccentric itself, which is so keyed to the shaft as to revolve with it. This is surrounded by a hoop, so fitted to it as to allow the eccentric to slide round within it, and to the hoop is attached the straight bar a, on which the valves or other mechanism to be worked by it. The dotted circles show some of the positions assumed by the eccentric as it revolves upon its axis, and the points a', a", a"" indicate the positions successively occupied by the part of the eccentric marked a, which is the part farthest from its axis. The distance from a to a" marks the extreme length of the longitudinal movement of the rod attached to the eccentric. For some purposes the periphery of the eccentric is not surrounded by a hoop, but is immediately made fast to the tail of a long bar b, which may be provided with a friction-roller to facilitate the motion. Eccentrics of the latter kind are not necessarily circular, but may have any figure that can be required for modifying the motion of the apparatus attached to them. A bearing, as indicated in Fig. 14, is sometimes used; the eccentric being marked under Thwaites, vol. xxvi., p. 401, and many of similar forms are used in winding and spinning-machinery. Elliptical wheels, which may be used either plain or toothed, may be compared in their action to double eccentrics, or to two eccentric parts working for the purpose of raising and lightening, or they may be made to produce two rectilinear motions in each direction for every revolution of the shaft, whereas an ordinary eccentric produces but one. In silk-twisting machinery a peculiar kind of motion is produced by the use of two elliptical parts, one of which is worked on the other that the long axis of the one is opposed to the short axis of the other; so that while the axes or shafts upon which they are fixed are always at the same distance apart, the toothed peripheries of the wheels, notwithstanding their elliptical figure, are always in contact. By this ingenious arrangement the relative velocities of the two wheels are continually passing through a series of changes, which assist in the proper disposition of the thread upon bobbins.

The escapement wheels of clocks and other and several varieties are given under Horology, furnish types of another important class of wheels for modifying motion; and small-wheels (such as that marked a in Fig. 2 of the above article), pin-wheels, ratchet-wheels, and hose-wheels, all of which exist will be found in the works of artisans are among the ingenious contrivances by which the rotatory motion of a wheel and axle may be made to set to motion a train of complicated machinery, or to regulate and vary motion at pleasure. Ratchet-wheels are not only important when, as in the mechanism of the time-pieces, it is desirable to move one part of a machine backwards without affecting the rest, but they are also very important in cranes, jacks, and other machines for lifting heavy bodies, in which they are applied in such a way, in connection with regular escapements, that the parts of each are moved rapidly backwards and forwards, as to prevent the machine from running back when the moving-power is suspended for a time. In the common reciprocating saw-mill (Saw-Mill, vol. xx., p. 478), a ratchet-wheel, driven by a pull worked by an eccentric, is employed for moving the barks of timber a little between each stroke of the saws.

We now come to the consideration of wheels employed for the purpose of diminishing the effects of friction and inertia, such being the third class of wheels alluded to in the preceding article. The two main divisions of this subject are, first, the reduction of friction, and second, the diminution of inertia. Of what are commonly, but incorrectly, styled friction-wheels and rollers, generally, it may be observed that they diminish resistance by converting what would otherwise be a rubbing into a rolling contact, a property possessed in the faces of the various kinds of friction surfaces which are used in machinery and by the wheels of a carriage. Theoretically speaking, the same principle is exemplified in the use of oil and grease applied to diminish the friction of axes and bearings, since they effect the desired object by interposing between the surfaces which would otherwise come in contact, gas or vapor, in such a manner that the particles of which the surfaces are composed act as friction-rollers of infinitely small diameter. When the surfaces of two bodies are caused to pass over each other with a rubbing or sliding motion, their inequalities necessarily meet and oppose each other, and thereby cause resistance to the sliding motion, and wear of the opposed surfaces; and however smooth these surfaces may be, such resistance and wear will take place. In a material substance, or if the roughness of the surfaces should require a system of rollers or wheels, be applied between them. In such a case, full rolling contact such destructive attrition is obviated, because instead of the impressions which it being dragged against those of the surface itself, the rolls, they are successively, as it were, the particles and lifted up from them. Friction-rollers, which may be as large, but are not necessarily fixed, may themselves be made to roll upon the rolling surfaces, or interpose between the inherent motions, whether the two surfaces are interposed bodily between the peripheries of the wheels, or are not interposed, and the friction is transmitted through some intermediary medium, as in the case of the saw-mill.

Fig. 13.

Fig. 14.
The action of the friction-rollers is to interpose pressure upon the peripheries of the rolling bodies in all cases where the relative motion of both is designed to be interfered with. They do not entirely destroy rubbing or sliding friction, but remove its action to a smaller and smoother surface. Thus, in comparing the action of a wheel-carriage with that of a sledge, it will be seen that the extent of the rubbing made by the friction of the flat seats of a sledge is diminished in proportion to the circumference of the wheel and that of its axle, while the amount of resistance is further diminished by substituting smooth surfaces of metal, which may be lubricated with oil or grease, for the rougher surfaces of the road and those parts of the sledge which lie in immediate contact with it. When friction-rollers are employed to diminish the friction of a shaft or axle in its bearings, six of them may be arranged at equal distances round the circumference of the axle, and the friction of the parts so diminished as to prevent the escape of dust. In some cases the friction of axles or shafts is diminished by the use of friction-wheels, which act in a similar way to the wheels of a carriage, but more by diminishing the velocity and the extent of the rubbing surface than by reducing the friction itself. A sufficient illustration of this use of friction-wheels is given in the article Artwool, vol. iii., p. 71, in the machine contrived by him for measuring accelerated motion, where the axle of a pulley, instead of resting in ordinary bearings, rests upon the peripheries of a series of wheels, the axles of which of course revolve with greatly diminished velocity. Various plans have been tried for applying friction-rollers and friction-wheels to wheel-carriages so as to assist them in carriages, to diminish their axle-friction; but while some were invented on a small scale, with accurately formed models, many indicate an important advantage from such mechanism, the writer is not aware that any plan of either kind has been found generally applicable. There are advantages of a very considerable extent in the construction of fly-wheels. They are very commonly made of cast-iron, and for that material a velocity of eight feet per second may be very safely applied. Tredgold states that if a velocity exceeding twelve feet per second be required, the arms of the wheel should be of wrought-iron; and that thirty-three feet per second is the utmost velocity that can be safely given to a fly-wheel of which the rim, as well as the arms, consist of wrought-iron. Where fly-wheels are mounted upon shafts turned by cranks, it is also necessary to provide a counterbalance of a weight sufficient to equalize the resisting force. In some cases the counterbalance is merely the weight of the rim of the fly-wheel, but in others it is provided by a mass of metal that is made to revolve in the same manner as the rim of the fly-wheel. The action of these rollers resembles that of the rollers employed by quarry-men and masons in moving large blocks of stone; and one of the peculiar features of the construction of the wheel is the connection of the rollers with an endless chain, which not only keeps them from rolling forward or backward, but also moves them to and fro as required, the arms of the chain being moved by the motion of the engine. Full particulars are given in Hebert's "Engineer's and Mechanic's Encyclopedia," art. "Railway."
disc, such as might be procured by a transverse section of the trunk of a tree of tolerably regular form. Adams, in his work on "English Pleasure Carriages," gives a representation of a rude car with wheels of this kind, which is used for agricultural purposes in Ohio. Solid wooden wheels are still occasionally used in machinery, but if large they are usually formed of two or three thicknesses of planking fastened together, with the grain crossing in various directions. It is the practice to use the wheels for millwork, when not required to be solid, usually bound together, some fastened to the inner or outer sides, the inner sides or edges of which are left straight. The periphery may consist of three thicknesses of planking, each composed of six or eight such segments; and if the spokes be of sufficient length, a wheel of considerable strength may be thus produced. The arms or radii of the wheel are fitted to the inner or outer sides of the segments by bolting or other modes of fastening.

Wooden wheels are occasionally morticed into their slots for the centre; but a pastural plan is to use four arms arranged in two pairs crossing at right angles and hallowed into each other in the centre, where their intersection leaves a square opening for the shaft. This opening should be somewhat larger than the shaft itself, and the difference of size the like as a means for increasing or decreasing which afford the means of adjusting the wheel perfectly true upon the axle. In very large wheels, such as water-wheels, two complete sets of clasp arms, one on each side of the wheel, are used. In mounting face-wheels it is not unusual to support the whole weight of the wheel at a point some distance along the shaft, to resist the tendency of the trundle or pinion to force the wheel out of its true position at right angles with the shaft. Horsbeam is made to be the best kind of wood for the cogs or teeth of wheels.

In modern machinery cast-iron has almost entirely superseded the use of wood for cog-wheels of every description. If they do not exceed eight or ten feet in diameter, they may be cast in one piece, and the teeth be made movable so as to increase or decrease which size it is desirable to form them in two or more parts, because of the difficulty of cooling a very large casting without unequal contraction. Where the diameter does not exceed twelve or fourteen feet, the rim may still be formed in one piece and the teeth be morticed into it, the two to be bolted together. Large iron wheels are adjusted accurately at their axes by wedges or keys, but small ones may in many cases be adjusted by turning the periphery in a lathe after mounting. When cogs are cast upon a wheel, it is not unusual to make them cast one piece, but an economy is gained by having them cast separately, and then to reduce them to the proper size, and to a truer figure than could be obtained by casting, by chipping them with a cold chisel, and filing; but a serious objection to this plan is, that it removes the external crust of the iron, which forms a casing-case-hardening, and so exposes the teeth to rapid wear.

Carriage-wheels are the wheels in which the greatest amount of construction is called for, as they are exposed to strains far greater for their size and weight than almost any others. The peculiar nature of these wheels requires not only that the wheels be made exceedingly strong, but also that they possess a degree of elasticity sufficient to enable them to bear the violent concussions to which they are often subjected, and in which the wheel is occasionally bent out of the starting of any of their numerous joints. An ordinary carriage-wheel consists of the nave, a cylindrical block of wood, usually elm, which forms the centre of the wheel, and which is pierced longitudinally with a hole to receive the axle. The nave is framed into the nave at equal distances; and the felloes, which are circular segments framed on to the outer extremities of the spokes, and forming collectively the periphery or rim of the wheel. The external surface of the felloes is usually protected by a covering of iron, called the tire, which may either be put on in several pieces, or traced, the joints of which are made to alternate with those of the felloes, or in a single piece, forming a hoop.

The simple joint to which this tire could be formed would be that in which the spokes would stand at right angles with the axis, and would form a flat or plane figure when the wheel is viewed edgewise; but such a wheel would be ill adapted to meet the lateral shocks to which a carriage-wheel is exposed. The more common form is that called the disked wheel, in which the centre or nave is made to fall back a little from the plane of the felloes, so that the face of the wheel is not flat, but slightly concave. The elasticity of this form is a very great recommendation, and it possesses also this advantage. When the axe of the wheel is slightly bent down towards its extremity it is impossible for the lower half of the wheel to carry a nearly vertical position, which will enable them to bear the greatest possible weight, the upper half of the wheel will have such an inclination as to throw particles of dirt, caught up in its revolution, away from it. A further advantage of this arrangement is that such a wheel, mounted as described, is not likely to exert injurious pressure upon the linch-pin or other contrivance retaining it upon the axle, since the weight tends to keep the wheels upon their axes without any aid from the linch-pins. Very strong wheels are occasionally made in a double-dished form, or with the spokes alternately inclining outwards and inwards from the felloes, so as to lie on the nave or nave of the wheel the base of a pyramid of which the felloes forms the apex; but such wheels are very deficient in elasticity, and consequently will not bear much concussion. In ordinary dished wheels the spokes are arranged in two sets, being alternately more upright and more inclined towards the nave, and the lateral spokes are sometimes set absolutely straight or square with the nave. The dished form of wheel, together with the bending of the axle, involves some increase of axle friction, and the use of the wheel with a circular tire, which cannot possibly roll in a straight line without a degree of rubbing friction most injurious to the road, and which also increases the draught. Some years ago the use of conical wheels for wagons, combined with the inordinate breadth of the ground and the numerous legs of the carriage, increased to a most absurd extent, and broad-wheeled wagons were used which were far better adapted for grinding stones into dust and mud than for the purpose of locomotion. This extravagance has now seldom seen, and for right reasons, the general opinion is, that a wheel of the ground is greater in proportion to the bulk and strength of the wheels than in any others, the use of moderately dished wheels can hardly be said to be attended by any practical inconvenience. The tires of such wheels are often rounded, so as to have an exceedingly narrow bearing upon a firm hard road.

Few mechanical operations of equal complexity, and requiring an equal amount of precision, have received so little aid from machinery as the manufacture of carriage-wheels. Even in the times of the great Cyrus of Persia, at Pirimico, near London, for making wheels by machinery, and although the nature of the operations is kept strictly secret, they appear to be of a most satisfactory character; the wheels produced being very superior in truth, firmness, and durability to any other, but have not shown sufficient proof of the statement, that in addition to the superiority occasioned by the application of the machinery to the fitting of the several parts, the wheels produced at these works are put together by pressure only, without the aid of percussion. In ordinary wheels the neatness and strength is increased by the application of a hoop of iron to each end of the nave, to enable it the better to resist the strain of the spokes. The spokes, which are usually formed by turning the nave, are set in proper form after being driven into the nave, and are usually cut to a narrow edge in front to lighten their appearance. Wheels have been made with the periphery or two pieces, or two pieces, bent into the required form, but have not been found successful, because, among other disadvantages, the wood is injured by the long boiling required. In high, coach-wheels, from 4 feet 3 inches to 4 feet in bore, there are 14 spokes, and the foot lower, there are commonly 18 spokes, and the usual arrangement is to have half as many in the nave, and as spokes. The felloes are dovetailed further secured by inserting an iron hoop, and by the hoop tires, which are a system of hoop-making, as it is called.
the whole of the wheel together with irresistible force. The tire is made very hot, and the wheel is made of such a size as only just to receive it when it is thus expanded; but so soon as the hoop is brought into its proper place, water is thrown upon the wheel to cool the tire, and to prevent the wood-work from catching fire, and the rest of the sudden contraction of the hoop is to compress the fellos, and to force each spoke into a slightly curved form, so that when the complete wheel forms a flat dome-shaped figure, admirably adapted, by its combined strength and elasticity, for the purpose for which it is designed. The tire is further secured, after cooling, by a few pins driven through it and the fellos, and riveted inside the latter.

While the importance of a certain degree of elasticity in wheels cannot be too much insisted on, it is an error to suppose that this advantage cannot be obtained from plain iron springs of the carriage in the wheels, as several ingenious inventors have proposed. On this point see SPRING-CARRIAGE, vol. xiii., p. 388.

Having found during his experiments on steam locomotion upon the principles of the railroad, the construction were not strong enough for his purpose, Mr. Hancock contrived and patented a wheel in which the nave is abandoned altogether, and the inner ends of the spokes are formed into wedges which abut against each other, and are held together by a kind of arm in the form of a box. These are firmly secured in their places by an iron plate on each side of the wheel, and a bolt passing through each spoke. Though too rigid for very rapid motion, this wheel is exceedingly strong, and its simplicity of construction makes sensible to the hands of the great recommendations of it.

The rapid motion of railway carriages, coupled with their great weight, so greatly increases the effect of such conclusions as must occur on even the smoothest road, that the wheels have often been found to fail them. Cast-iron wheels have been much used on colliery railways, and in some cases where rapid motion is required; but while they may be made abundantly strong, as far as the direct pressure is concerned, their brittleness renders them very liable to injury when passenger horses are employed; plans for the combination of wrought-iron and cast-iron in the same wheel have been devised; but while some of these have been brought into operation, wheels entirely composed of wrought-iron have been by far the most generally adopted. The facility with which that material may be worked into any form has led to an endless variety of plans, some of which are highly ingenious, for combining the requisite degree of strength and elasticity. In some wheels the annular space between the central boss or nave and the rim is filled up by a series of octagonal floats, of thin bars of iron, abutting against each other; in others there are spokes, but instead of consisting of single rigid bars, each consists of two halves, having a slight degree of curvature. By these and similar contrivances elastic force is given to the wheel, and without distorting the form of the wheel, it is evident that the wheels might revolve on axes at right angles to each other. This construction is at present in use for some kinds of machinery; occasionally also the teeth consist of small blocks of wood let into the annular spaces on the external face of the wheel, and without the edges cut off diagonally, so that each block has the form of half an octagonal prism. A small wheel having cylindrical staves, or spindles, fixed between two circular bands or plates of metal, in positions parallel to the axis of the wheel is called a spur-wheel: but when the teeth are perpendicular to the plane of the wheel, the latter is called a crowned or contrate wheel. If the teeth are cut on the circumference of a wheel, in a direction oblique to its plane, the wheel is said to be crowned, and the name of contrate is derived from the manner in which it is to be carved in planes making any angles with one another.

The least attention to the manner in which the teeth are cut on the circumference of two wheels act against each other. In the ends of the teeth the advantages the force of the teeth is to be felt only when the acting faces of the teeth some advantages would be gained in respect of the steadiness of the rotation; and Blore, in his "Treatise on the Epicographia," mentions that he saw at a piece near Paris a machine executed with cast iron but the name of the man who invented the form of the curve which was employed is not explained. Montelena offers a conjecture that the Danish astronomer Rømer was the first who made the remark that the epi-epicographia form is the most proper for the acting faces of the teeth of a wheel.
and he states that such a remark occurs in a memoir which was read at a sitting of the Académie, in 1675. This conjecture is supported by a passage in the works of Wolfius (tom. 1., p. 654), and by the evidence of Leibnitz, in the "Comm. Philos.," tom. ii., p. 178: the latter observes that while he resided at Paris the merit of the discovery was ascribed to Römer. La Hire however asserts, in the work above mentioned, that he had discovered this property of the epicyclic in 1674, and had communicated it to several mathematicians.

Besides a uniformity of action in which the teeth of wheels should exert upon one another, their figure should be as little as possible liable to derangement; they should consequently be made of metal rather than wood. It has been thought however that in the larger kinds of machines the action is more gentle if the teeth of one wheel are made of hard wood, and those of the other of cast-iron; both the wheels being of the latter metal. The irregular shocks to which a toothed wheel badly constructed is liable, are the causes that a considerable part of the work may be done by a machine, and this evil is diminished by having the teeth in each wheel as numerous as possible; the number will however depend on the magnitude which each tooth must necessarily have in order that it may possess the requisite strength. When a toothed wheel drives or gives rotation to a pinion, the ratio between the radii of both will depend upon the power or the velocity which may be required; but the disposition of the wheel and pinion should be such that the pressures of the teeth mutually exert against each other is the least possible; and the form of the teeth should be such that the moving power at the circumference of the wheel may bear a constant ratio to the resistance at the circumference of the pinion.

When a wheel is employed to drive a pinion, the pressure on the pivots of its axle is the resultant of the weights of the wheel and whatever is attached to it, the pressure of the moving power applied at its circumference, and the pressure of the moving power applied at its circumference; it is evident therefore that if the pinion is placed on the same side of the axle of the wheel as the moving power, the latter acting vertically, and if the axes of both wheel and pinion are in the same horizontal plane, the results will be the least possible; for it will be equal to the weights of the wheel together with the difference between the downward pressure of the power and the upward re-action of the teeth of the pinion against those of the wheel at the place of contact. But if the pinion be on the opposite side of the axle of the wheel, the pressure upon this axle will be the greatest possible; for it will be equal to the weight of the wheel together with the sum of the moving power and the re-action of the teeth of the pinion, all of which in this case acts in a direction opposite to the support of the wheel will be less when the wheel and pinion are in the same plane, than when they are perpendicular or inclined to each other; for in the first case the pressure is perpendicular to the axis, but in the other the obliquity of the action produces a considerable strain on the wheel. When the same wheel drives two pinions, the most favorable positions for these last are those in which their axes are in the same plane as the axis of the wheel. When however the latter axis has a great burden to support, it may be advantageous to dispose both the pinions on one side of a vertical line drawn through the axis of the wheel; for then the re-action of the pinions upwards will tend to diminish the pressure on the supports of the axle.

The above considerations, or the radii, of two circles which are to act upon each other like a wheel and pinion, is known from the power, or velocity, which is to be obtained: the distance between the centres of the two circles is also given. Therefore if a line as AB is drawn, and this line may be considered as if so that AX shall have to BM the given ratio. The circles whose radii are AM and BM are called the pitch or primitive circles; and by these the places and forms of the teeth are determined.

If the number of teeth for a wheel or pinion is given, and also the distance PQ between their middle points, supposed to be measured as a chord of the primitive circle, the radius of that circle may be found; for if n be the number of teeth, \( \frac{360}{n} \) or \( \frac{180}{n} \) will give the angle PAR subtended by half that chord, and, by trigonometry, rad. (\( = 1 \)) = \( \cos \theta \) \( \frac{180}{n} \) :: PR : AP, and AP is the required radius of the primitive circle.

When it is required to produce a considerable angular velocity with the smallest quantity of wheel-work, the diameter of each wheel should be eight or nine, or four times as great as that of the pinion on which it acts, and a pinion should have not less than six or eight teeth. It is recommended also that the number of teeth in a wheel be not an exact multiple of the number in the pinion; since then each tooth of the wheel will act successively on different teeth of the pinion, and thus the latter teeth will be less worn than if the same teeth were constantly met in each revolution.

One of the most simple ways in which a wheel may impel another is that in which the teeth of the first wheel work between the cylindrical staves of a lantern; and it may be easily shown that, in this case, an epicycloidal form is the most advantageous for the acting faces of the teeth. For let A in the above figure be the centre of the first wheel and B the centre of the lantern; also let AM and BM be the radii of the primitive wheels, or of such as would be constructed to produce the required power if one of the wheels moved the other by means of a strap passing over their circumferences, or by the friction of their circumferences at the point of contact. Then, if the diameters of the staves in the lantern are supposed to be infinitely small, and if MN represent a side of a tooth coming first in contact with such a stave at M in the line of the motion, the motion of the wheel will have been as the arc MN will be brought into the position MN', for example, when the lantern being turned about B in the direction DM, the stave at M is impelled forward to some point m, so situated that the circular arcs MM' and MM are equal to one another. Let now the arc MB be such as would have been described by the point m if the circle CD had rolled on the circumference of AC from the time that m was in contact with C till the centre B came to the position which it has in the figure; then it is evident that MM' or MN will be a portion of an epicycloid, of which BD is the epitrochoid, or generating circle, and AC the deferent [TROCHOIDAL CURVES], and it is a property of such curve that a normal to it at m (any intersection of the generating circle with the curve) will pass through the point of contact M of AC and BD. Let also the straight line MM' be the radius of curvature for the point m. Hence if one face of a tooth on the wheel AC have the form of such epicycloid, the pressure exerted on the stave of the lantern will be always in the direction of a line drawn through M and the stave in contact with the tooth: the action of the tooth on the stave is therefore direct, or without any sliding movement; and because the arc MM' is always equal to the arc MM', the angular motions of the circles will be the same as in the direction of AC the circumferences or radii, or the rotation of the form will be uniform when that of the wheel is so.

Since the staves in the lantern must have a greater radius, as MN, a curve equal and similar to that passing through m will serve for the form of the staves. Such curve may be traced by rolling the circle AC round MM' into any number of equal arcs as centres drawing straight lines MN' to MM; a line as on touching all these curves through M with AC.
required curve. If it be intended that a tooth of the wheel AC should not act upon a slave of the lantern till a arrives at M in the line AB, the centre of the slave should be placed so that a may be where M is; and then about half the slave, on the right hand of the diameter passing through it, being unnecessary, it may be omitted, and the slave may consist of about half a cylinder: if however the slaves are made entire, notches must be cut between the teeth of the wheel AC in order to allow them to pass while the wheel is revolving. If Pp, Qq represent two teeth formed as above described on the circumference of the wheel, the distance between them must be such that the face p may begin to act on a slave immediately upon the face q quitting it.

The correct formation of epicycloidal teeth is perhaps seldom attempted in practice; the curve however may be easily traced by means of its equations, which, agreeably to the notation employed in the article on TROCHOIDAL CURVES, are

\[ x = (a + b) \cos \phi - b \cos \frac{a + b}{b} \phi, \]
\[ y = (a + b) \sin \phi - b \sin \frac{a + b}{b} \phi; \]

where \( a = AM, b = BM, \) the angle \( M'AB = \phi; \) and \( M'B \) being let fall perpendicularly on \( AM' \) produced, \( x = AM = b \phi. \)

If it were required to turn a pinion by the revolution of a wheel, the teeth of both having like forms, and it were also required that the teeth of the wheel should commence acting on those of the pinion at the instant when the point of contact is in a line joining the centres A and B of the wheel and pinion; it may be easily shown that, in order to produce uniform movement, the acting faces of the teeth should have the form of epicycloids. Thus, let AC, BC be the radii of the primitive wheels, and let CD be an epicycle of any convenient magnitude; let also Cm, Cn be epicycloidal arcs, the former supposed to be described by the point C in the circle CD, as this circle revolves on the exterior circumference of the deferent circle AC in the direction CE, and the latter by the same point, as the same epicycle revolves in the interior circumference of the circle BF in the direction GF, the line CB being a tangent to both arcs. Then let P and Q, on the circumferences of the circles AC and BC, be two situations of the point p in the epicycle, at an instant when the three points are in contact at P; and let Pq, Pa be arcs similar and equal to Cm and Cn; these will be described by the point p when the epicycle rolls on one circle over the other arc PC and on the other over the arc QC. Now it is demonstrated by mathematicians that a normal to an epicycloid at the point where it is cut by the circumference of the generating circle passes through the point at which this circle is in contact with the deferent; therefore the straight line AC will be a normal to both the arcs Pq and Pa, or those arcs have the same tangent at the point a; that is, the arcs are in contact with each other at every point a in which they meet; and since the equal arcs Cm, Cq are described in the same time, it is evident that, as in the former case, the wheel and pinion move uniformly.

A wheel and pinion formed in this manner would be such as is represented in the annexed cut: the point C in in the one of the wheels begins to act at the point C of a tooth in the pinion; and in moving from C to P the former tooth drives C' to Q, where these teeth cease to act on one another. During this movement the surface Cm or Pn' is in contact with C'n or Qn' in one point; consequently no friction takes place between the surface or only that which arises from the imperfect formation of the teeth.

The arcs Ca or Qa in the preceding figure, or the arcs C'n, Qn' in the present figure, are called hypocycloids but as the generating circle CD above may have any magnitude, let CD, its diameter, be equal to the radius CB of the pinion; then the hypocycloidal arcs become straight lines in the directions of diameters of the circle CB: in which case the teeth of the wheel should be epicycloids described by a generating circle whose diameter is CB, and the acting faces of the teeth of the pinion should be planes passing through B, as in the annexed cut.

The uniformity of action can however only take place between the faces near the line AB which join the centres of the wheels; any point of contact at the same time will be subject to small irregularities and a certain amount of friction.

If it be intended that the teeth of the wheel shall bear to act on those of the pinion before the point of contact on a given tooth arrives at the line AB, and shall terminate when it comes to that line, the reasoning before used may be applied; it being necessary merely to consider Br the larger wheel, and AC as the pinion, so that now the faces of the teeth in the wheel are hypocycloids and the corresponding faces of the teeth on the pinion epicycloidal: then Q (Fig. 3) must be considered as the point of contact, and C the point at which the action of the tooth on Pn or Cn terminates. The acting faces of the teeth of BC, considered now as the wheels, must be planes leading to the axis of that wheel, as in Fig. 4, in which case the diameter of the generating circle by which the faces of the teeth in AC are formed must be equal to the radius CB of the larger wheel. The labour of the formation is much diminished by this disposition of the teeth on the wheel and pinion; for the large wheel contains the greater number of teeth, and these have less plane faces.

In forming the epicycloidal arc Pq, Fig. 2, from the above equations, it must be observed that AC = a, GB = AB = x, and Ha = y. The hypocycloidal arc Qq may also be described by means of its equations, which are the same as the equations for the epicycloid, except that for \( a + b \) read \( a - b \), and the sign of the second term in the expression for \( x \) is positive. Here \( BQ = a, GC = b, \) the angle \( CBq = \phi, \) \( BK = x, \) and \( Ka = y. \)

The involutes of circles which were prepared by the Robison for the form of teeth, have some advantages over the constructions above mentioned, measured as a great number of such teeth can be made to act at the same time, and thus the pressure on each is diminished. In order to describe these involutes, let A be the centre of the wheel and B that of the pinion; let also AC and BC...
be the radii of the primitive wheels: from A and B as centres describe circles whose radii AM and BN have the same ratio to one another as AC has to BC, and draw the straight line XY touching these last circles. Then if a flexible line coinciding with the circumference of the circle AM be unwrapped, let its extremity M may describe the curve MN, and another such line coinciding with the circumference of the circle BN be unwrapped so that its extremity N may describe the curve Nn; those curves MN and Nn will be the required forms for the acting faces of the teeth, and the faces will be always in contact with one another in a certain point C in the line XY, which from the nature of the curve is a common normal to both: the pressures of the teeth against each other will always be in the direction of that line (which is a common tangent to the two circles) as if they were applied in that direction at the extremities of the radii AX and BY; and the angular motions of the two circles will be to one another in the constant ratio of those radii, that is of AC to BC: consequently the motions will be uniform.

In Dr. Young's 'Lectures on Natural Philosophy' (vol. ii. p. 53) it is shown that when the teeth of two wheels are in the form of the involutes of circles, the relative velocities of two teeth in acting on each other, or the velocities with which their acting surfaces slide on each other, vary, when one wheel moves on the exterior circumference of the other, with the sine of the sum of the two angular distances of the points of contact from the line joining the centres of the two circles. If one wheel moves in the concave circumference of another, the relative velocities vary with the sine of the difference between the angular distances. It is added, that the mechanical effect of friction in resisting the motion of a machine is so much the greater as the relative velocity is greater.

In general the teeth of a wheel AC are made to act on the teeth of a pinion BC before the place of contact arrives at the line joining the centres of the circles, and to continue the action for some time after that arrival: in this case it is evident, from what has been before said, that ab should be part of a hypocycloid formed by any generating circle rolling on the concave circumference MN of the primitive wheel, and bc should be part of an epicycloid formed by any generating circle rolling on the convex circumference of the same wheel. The portion ab of the circumference of the pinion should be part of an epicycloid formed by the first generating circle revolving on the convex circumference RS of the primitive pinion, and be part of a hypocycloid formed by the second generating circle revolving on the concave circumference of the same pinion. To avoid however the trouble of forming the face of every tooth with two different curves, La Hire recommends that the parts ab and be be plane surfaces, as if the diameter of the generating circle for describing the former had been equal to the radius AC, and the diameter for describing the latter had been equal to BC. This is also the construction recommended by Buchanan, in his 'Treatise on Mill-work.'

Since a straight line may be considered as part of the circumference of a circle whose radius is infinite, an epicycloid formed by a generating circle rolling on a straight line becomes a cycloid; and hence it is evident that if a piece of rectilinear rack-work be employed to give motion to a pinion, its teeth should have their acting faces cut in the form of a cycloid, whether the teeth of the pinion be small cylindrical staves, or have plane faces trending to the axis; but in the former case, the radius of the generating circle should be equal to that of the pinion, and in the latter it should be equal to half that radius.

If a wheel to turn surfaces tend to make two teeth in the circumferences of both, and the planes of the two wheels are to make with each other any given angle, the acting circumferences of the wheels must evidently be frustrums of cones which have a common vertex at the point where the mathematical axes of the former wheels are produced. The numbers of revolutions which the two wheels are to make in the same time are supposed to be given; and, by mechanics, the radii of the wheels must be inversely proportional to the numbers of revolutions: therefore these radii are known.

Let A and B be the centres of the wheels, CA and CB the axes of the revolving cones, of which C is the common vertex; and let AD, BD, perpendicular to CA and CB, be the radii of the wheels on their exterior faces; then CD will represent the line in which the convex surfaces of the two cones may be supposed to be in contact, and its position may be determined, since it divides the given angle ACD in two parts ACD and BCD, which have to one another the given ratio of AD to BD, or so that

\[
\sin \angle ACD = AD \div BD \times \sin \angle ACD.
\]

The conical surfaces of the wheels being cut into teeth having directions tending to the point C, the wheels will mutually act upon each other to produce revolution. For simplicity, let it be supposed that the teeth of the wheel DP are in the form of small conical staves or spindles whose axes and convex surfaces pass through the point C: then if a spindle were supposed to be a mathematical line, the conical surface described by such line in its revolution about CB, from the time that it is in contact with the oblique surface of DP, would be the form to be given to the acting sides of the teeth on the latter surface; and a curve surface of like form imagined to be situated under the surface so described, at a distance from it, at every point, equal to the semidiameter of the conical spindle at that point (the spindle having a given magnitude) will be the required figure of the acting surfaces. The curve line traced by either extremity of the axis of a spindle during the movement is called a spherical epicycloid, being on the surface of an imaginary sphere having C for its centre.

In the formation of such machines the generative motion is not required; and in such cases the wheels are either divided by the teeth unequally on the circumference, or the axes on which they revolve are placed at certain distances from the mathematical centres of the wheels.

The principal writers on the mathematical principles of the teeth of wheels are, La Hire, 'Traité des Epicycloïdes;' Camus, 'Cours de Mathématique;' and Euler, 'Novi Comment. Petrop.'

WHETSTONES are a smooth flat stone used for whetting or sharpening edged instruments by friction. Whetstones, Vol. XXVII. - 2 T.
which are sometimes called *hones*, are made of various kinds of hard close-grained stone, and are moistened, when in use, with either oil or water. The latter is preferred by some, because it permits closer contact between the stone and the metal, but as it allows closer contact between the stone and the metal, it does not appear so well adapted for producing a very smooth surface. The proper use of a whetstone involves a degree of skill and dexterity which can only be obtained by long and frequent practice in the art. It is very generally considered as a necessary part of a joiner's trade, and as a whetstone is experienced in the use of a common whetstone to set or sharpen razors, pen-knives, &c. with facility, Mr. Fayer, of Pontefract, contrived some years since a hone consisting of a stone mounted in a bar of brass, the ends of which are filed into round pivots, which rest in bearings attached to the mounting of the hone. One side of the bar is made smoother than the other, and in order to use the hone, the roughest side is first turned uppermost, and a little of the hone is taken over the bar, and the operation repeated upon the smoother side, with finer powder of either the same kind of stone or of that known as water of *Ayr* stone. As the whetting proceeds, the powder becomes finer and finer, and therefore gives to the hone an increase of the roughness of the stone. For convenience, the mounting of the hone is provided with two small boxes to contain a supply of powdered stone.

**WHIG.** [Chrest.]

**WHICHCOTE, BENJAMIN, D.D.,** was the sixth son of Christopher Whichcote, Esq., of Whichcote Hall, in the parish of Stoke, Shropshire, and was born there 11th March, 1610. He studied at Emanuel College, Cambridge, where he was admitted in 1626, and of which he was elected a Fellow in 1633. Having taken his degree of B.D. in 1649, he was in that year, or early in the next, admitted to the living of Shrewsbury, in Shropshire, which vacated his fellowship, he went to reside there, and married; but early in the next year, on the election of Dr. Samuel Collins from the provostship of King's College, he was admitted to the extraordinary fellowship of that college to the rectorcy of Milton, in Cambridgeshire, on which he resigned his Shrewsbury living. At the Restoration Dr. Whichcote was removed from his provostship by the new government, rather to mark their disapprobation of his sermon at the public ordination, in 1660, in which he had offered, in words which the chancellor had written, that the man or his conduct, for he had never signed the Covenant, nor taken part in any of the violent proceedings of the times. He retained his rectorcy of Milton, and, coming up to London, was chosen minister of St. Anne's, Blackfriars. From this church he was burned out by the great fire in 1666; but two years after he was presented by the crown to the vicarage of St. Lawrence, Jewry, on the promotion of Dr. Williams to the bishopric of Chester. He died while on a visit to Cambridge, at the house of his friend Dr. Cudworth, master of Christ's College, in May, 1683.

Dr. Whichcote is regarded as one of the heads, if not the chief founder, of what is called the Latitudinarian school of English divines, as holding those views of Christianity which are distinguished by the two important characteristics, that they are liberal and toleran-
venereal in Scotland (from whence it was borrowed) for corrupt and sour why. In point of fact, whig, according to the Scottish lexicographers, is not whey, but the slightly adulterated serum of butter-milk.

Quite a different account from this however is given by Burns in his 'Tamburlaine the Great,' the Old Time (i. 48), under the year 1648, that writer says, 'The south-west counties of Scotland have seldom corn enough to serve them round the year, and the northern parts producing more than the need, those in the west came in the summer to buy at Leith the store there and from the word whiggan, used in driving their horses, that all were called whiggoners and shorter, the whigs. Now, in that year, after the news came down of Duke Hamilton's death, the Whig leaders animated their people to rise and march to Edinburghe, and the head of their parishes, with an unheard-of fury, praying and preaching all the way as they came. The Marquis of Argyle and his party came and beard them, they being about to drive the whiggoners inroad; and ever after that all that opposed the whiggars came in the court to be called whiggs, and from Scotland the word was brought into England, where it is now one of our unhappy terms of distinction.'

There can be little doubt that this is the true origin of the name Whig, and that it was really its previous application to the Scotch Covenanters that led to its revival as a designation for the opponents of the court in England in 1679. Kirkton, in his 'History of the Church of Scotland,' has noticed that the men white; and as the term may have been used of the English Tories of 1679 to carry a peculiar significance and appropriateness in reference to the sour and rigid temper which they attributed to their opponents, and the want of cordiality and substance with which they changed their principles, independently of its previous application to the Covenanters. There may have appeared to the common feeling, too, that being some of things in giving an object to the common-devices and warm-bloodedness of the royal prerogative, and a Scotch one to the more cool and argumentative wranglers for popular rights. It may be said with considerable truth that, nationally or generally, the name Scotch Whig is Whigs by temperament or mental constitution.

With regard to the party opinions of the Whigs, it is scarcely necessary to add anything to what has been stated under the word Tory. The Whigs of the last century and a half have been generally viewed as the representatives of the friends of reform or change in the antient constitution of the country, ever since the popular element became active in the legislature, whether they were called puritans, non-conformists, round-heads, covenanters, or by any other names. The revolution of 1688, the first of the Scotch Whigs were Whigs by temperament or mental constitution.

The Whigs of the last century and a half have been generally viewed as the representatives of the friends of reform or change in the antient constitution of the country, ever since the popular element became active in the legislature, whether they were called puritans, non-conformists, round-heads, covenanters, or by any other names. The revolution of 1688, the first of the Scotch Whig Whigs was to make such change; since that event, at least till recently, it has principally been to maintain the change then made. Of course however this party, like all other parties, has both shifted or modified its professions and changed its localities in concert. W I

WHIN. [ULEx.]
WHINCHAT, Saxicola rubetra, Auct., Motacilla rubetra, Linn.
Description.—Old Male.—Top of the head, sides of the neck, and upper parts of the body, blackish-brown; each feather with a wide border of rusty-yellow; above the eye an elongated streak of white, reaching to the occiput; throat and longitudinal streak on each side of the neck pure white; front of the neck and breast fine bright rusty; a great spot on the wings and tail of pure white; extremity of tail, as well as the two middle quills, and all the shafts, blackish-brown. Length nearly five inches.
Female.—With yellowish-white wherever the male has pure white; the white space on the wing less, and all the feathers with a small brown spot; the rust of the breast is less there, and the lower parts, as well as the upper part of the tail, are rusty white.
The Young have white and greyish spots all over their plumage.
This is the Grand Traquet, Traquet, Groulard, Tarier, Thyon, Semel (in Lorraine), of the French; Grosser Hingenfanger, Gestettenclag, and Braunhefliger Stein- schmätzer, of the Germans; Sultas-bastone con la gola bianco and Stiacone di Iicchini; Furzechat and Blackberry-eater of the modern British; and Clocher gr de l'ancien British.
Geographical Distribution.—Norway, Sweden, temperate Russia, but not Siberia: all southern Europe to the Mediterranean shore: common in Smyrna in winter (Strickland). In the British Islands they are generally, but not numerous in winter; abundant in summer; have been seen in the Hebrides, but are not recorded as having visited Orkney or Shetland. They arrive here about the middle of April; but, unlike the Stonechats, always, as a general rule, depart in autumn. Mr. Yarrell observes that the similarity in various points between the two species has induced a partial belief that the Whinchats, as well as the Stonechats, remain here during the winter, but he is not aware of more than two authentic instances of the Whinchat being seen here in that season: Mr. Nevill Wood records one, on the authority of Mr. H. Barlow, of Cambridge, in the mild winter of 1833. The last-named observer saw it hopping about near some furze-bushes in his neighbourhood, on the 15th of January and 20th of February, but only on those two occasions, though the common was visited on every clear day in those two months. The Rev. Robert Holdsworth, of Brixham, gave Mr. Yarrell the other instance: in a path near his residence at the entrance of the river Dart, in one of the warmest spots in England, the Reverend gentleman found a Whinchat dead during a very severe frost on the 20th January, 1829. The wind was north-east.
Habits, Food, &c.—The flight of the Whinchat is undulating, and it flies from bush to bush, perching on one of the topmost twigs. Furze common are its favourite haunts. Worms, insects, small shell-mollusks, and slugs form its principal food, but it also eats berries. The nest resembles that of the Stonechat, and is formed of dry grass stalks and a little moss, the lining being finer bents or stalks. It is usually placed on the ground; Mr. Sweet says that the old birds cover it with dry grass, so that it is impossible to find it without watching them. The eggs are five or six in number, bluish-green, with a few small dull reddish-brown spots. There are generally two broods, the first appearing towards the end of May.
The song is very pleasing, and resembles, according to Bechstein, that of the Goldfinch; and the bird will sing not only during the day, but in the evening, and sometimes at night. Mr. Sweet says, that such as are caught young may be taught any tune, or will learn the song of any bird they hear, but he does not think their own good. One that he bred from the nest learnt the song of the Whitebreast, Redstart, Willow Wren, Nightingale, and Musel Thrush, which it frequently heard singing in a neighbouring garden. Of this latter song it was so fond, that Mr. Sweet was frequently obliged to put his favourite out of the room, not being able to bear its loud notes. He speaks of it as the best bird he ever kept of any kind: it sang the whole year through, and varied its song continually; its only fault was its strong voice.
Whinchats become, like the Wheatear, very fat in August, and, though smaller, are equally delicate for the table.
In the Portraits d'Oiseaux the following quatrín is printed under the figure of this species:

Ex summiteles bolusse h lede
Inaccessim le Traquet on Tarier
Et le voyant sans cease varier,
Comme un tartouf de moullu on l'appelle.

The Whinchat: upper figure, female; lower, male.

Description.—Bill blackish; mouth very large, pale flesh-colour within, armed along the sides with numerous long, thick bristles, the longest extending more than half an inch beyond the point of the bill. Eyes, blackish.
Plumage above variegated with black, brownish-white, and rust, and colour, sprinkled and powdered with numerous minute streaks and spots. Upper part of the head blackish-grey, marked with a longitudinal stripe of black, with others passing out from it. Back darker, finely streaked with black in the sutures. Upper parts very light, yellowish-white, variegated with a few oblique black spots. Tail rounded (ten feathers, external 1½ inch shorter than those in the middle), the three outer feathers on each side black.
ab-brown for half their length, and thence white to their extremities; the exterior feather edged with deep brown with paler tips; the webs of the middle toes without white at the ends, but with herring-bone figures of black and pale ochre finely powdered. Cheeks and sides of the head brick-colour. Wings spotted with very light and dark brown, the pencilled white tips of the quills most visible. Across the throat a narrow white semicircle; breast and belly irregularly mottled and streaked with black and ochre-yellow. Legs and feet light purplish flesh-colour, seamed with white, feathered nearly to the feet, middle claw prominent. Middle toe 9½ inches, and the expanded wings 16 inches; female about an inch less. (Nuttall.)

**This is the *Weccolis* of the Delaware Indians; and *Whioppo-Will* of Lawson, "so named," says the latter, "because it makes those words exactly. They are the biggess of a thrush, and call their note under a bush, on the ground, hard to be seen, though you hear them never so plain.**

### Geographical Distribution.

**America.** Nuttall says that this species arrives in the Middle States about the close of April or beginning of May, proceeding in its vernal migration along the Atlantic States to the centre of Massachusetts, being rare, and seldom seen beyond lat. 43°; and yet, he adds, in the interior of the continent, according to Veildot, they continue as far as Hudson's Bay, and were heard by Mr. Say at Pembina, in lat. 49°. 'In all this vast intermediate space,' continues Nuttall, 'as far south as Natchez on the Mississippi and the interior of Arkansas, they familiarly breed and take up their residence. About the same time that the sweetly echoing voice of the Cuckoo is first heard in the north of Europe issuing from the leafy groves, as the sure harbinger of the flowery month of May, arrives amongst us, in the shades of night, the mysterious ***Whiop-poor-Will.***'

Mr. Clayton gave the following account of this bird, that he observed this bird on the northern shores of Lake Huron only, the fifteenth parallel being probably the limit of its range: it arrives, he adds, in Pennsylvania about the middle of April; the elevated dry 'Barrens of Kentucky' are its favourite resorts, and it is very common heard in the marshy tracts of the Susquehanna. Habits, Food, &c. — *Phalaroe* and other large nocturnal insects, beetles, grasshoppers, &c., &c., form the food of this night-jar. The two eggs, which are greyish white, almost covered by irregular and confusentumber-black bands and spots of the same size at both ends, are deposited about the second week in May in the Middle States, but considerably later in Massachusetts. There can hardly be said to be any nest, but the female selects some secluded spot in the forest, near a forest river, or a clear brook; and then, after she has alighted in the hollow rock, and always in a dry situation, according to Nuttall, who remarks, that this deficiency of nest is simply made up by the provision of nature, the, like parasites, the young are soon able to run about after their parents; and, when they are old enough, the parent (as is frequently so in countless numbers of the natural world) leaves them in charge to their own care, and only returns when they are able to follow him by the light of their own eyes. (Nuttall.)

### Check-Will-Widow, Caprimulgus Cardinarius. Cuculidae.

**Description.** The whole body-plumage sprinkled and mottled with brown, rufous, black, and white; on the tail are zig-zag and herring-bone figures of black. A slight whitish band runs across the breast; black, brown, and yellowish-brown, intermixed in various shades, the legs and feet being bright yellow. Length, 13 inches; across the expanded wings, 26 inches.

**Geographical Distribution.** Seldom to the north of Virginia, but in the interior extending up the banks of the Mississippi to the 38th degree. Arrives in Georgia and Louisiana about the middle of March, and in Virginia, early in April. Returns from the United States, probably to winter in some part of the tropical continent, about the middle of August.

### Chok-Will-Widow, Caprimulgus Cardinarius. Cuculidae.

**Description.** The whole body-plumage sprinkled and mottled with brown, rufous, black, and white; on the tail are zig-zag and herring-bone figures of black. A slight whitish band runs across the breast; black, brown, and yellowish-brown, intermixed in various shades, the legs and feet being bright yellow. Length, 13 inches; across the expanded wings, 26 inches.

Arrives in Georgia and Louisiana about the middle of March, and in Virginia, early in April. Returns from the United States, probably to winter in some part of the tropical continent, about the middle of August.
moon; and at the boding sound of its elfin voice, when familia-
and strongly reiterated, the thoughtful, superstitious savage becomes sad and pensive.'

The same author states that in rainy and gloomy weather these birds remain silent in the hollow log which affords them and the bats a common roost and refuge by day. When discovered in this situation, they ruffle their feathers, open their enormous mouths, and utter a murmur, almost like theissing of a snake, to intimidate the in-
truder.
The eggs, two in number, are laid on the ground, in the woods generally; they are dark olive, sprinkled with darker specks, oval in shape, and rather large in size. If they or the young be handled, the parents remove them to another place.

by four small pillars. The axle of the cylinder, which is of steel, passes through that plate, and terminates about four inches above it. To this is attached horizontally, and immediately upon the plate, a thin arm of wood or metal about four feet long, and formed with what is called the feather of ten or twelve, so that the extremity of the arm is affixed to the object which is to be used in the expen-
ment, and a wire proceeding from the top of the steel axle to the extremity of the arm serves to prevent the later from bending by its weight.

A silk thread made fast at one end to the surface of the cylinder is in part wound round the latter; the line then passes over a pulley fixed in a vertical position at the opposite extremity of the machine, and to its lower end is attached some given weight: the descent of the weight causes the cylinder, and consequently the cylinder to move. Any one of these he could at pleasure dispose so that either its convex or plane surface might be resisted by the air: there was also provided a flat plate of lead equal in weight to the hemisphere employed, which could be fixed to the arm when the hemisphere was removed, for the purpose of ascertaining the resistance opposed by the air to the motion of the arm itself.

The radius of the circle described by each hemisphere in its revolution is measured from the axis of the cylinder to the centre of the sphere, of which the revolving object is the half, and the radius of the cylinder is measured from the same axis to the middle of the silk line passing round the surface: let the latter radius be represented by r, and the former, when any one of them is in the same line of motion, by R. The time is marked by a stop-watch at the end of each revolution, and the differences between them are taken for the times of the revolutions. After a few revolu-
tions the differences are very nearly constant; and a mean of ten or twelve of these, thus found, may be considered as the time of revolution, when the motion is uniform in consequence of the equality of the resis-
tance and inertia to the weight of the descending body: let this weight be represented by W.

In order to discover the resistance due to the inertia of the machine and the action of the air upon the arm: the plate of lead, with its plane in a horizontal position, being fixed at the end of the arm, different weights are attached to the silk line, till some one is found which causes the arm to rise by uniform motion. The weight thus employed may have been observed to revolve when its motion was uniform. This weight, which may be represented by w, is evidently the equivalent of that resistance and inertia; and the difference W - w is the value of the resistance against the spherical surface of the revolving hemisphere only. The velocity of the latter is measured by the length, in feet, of the arc described by its centre in one second, and the weight or resistance W - w is sup-
posed to be applied at the circumference of the cylinder to which the silk line is a tangent. This term must re-
sequently be multiplied by R, in order to reduce it to the value of that which would be equivalent to it if applied at the centre of the revolving object.

From a mean of numerous experiments with a hemis-
D. Hutton found that the resistance of the air
against the flat side was to the resistance against the convex side as 2:48 to 1: by theory it should be as 2 to 1 only. From experiments made with hemispheres of different magnitudes, also with a whole sphere, a cone, and a hollow cylinder, it was found that the resistance experienced by a circular sphere was nearly that on the plane surface, 10 feet to 20 feet per second) were nearly proportional to the surfaces, increasing a little above that proportion with the greater surfaces; and that the resistances on the same surface were, at a mean, with the square power of the velocity, gradually increasing with the increasing velocities. When a hemispherical or conical surface was acted on by the air, the resistance was less than that which was experienced by a plane surface of equal diameter; but the shape of the body was very much the same. When a free ball, which was round: the convex surface of a hemisphere, for example, experienced less resistance than that of a cone, contrary to the result of theory. The resistance on the base of a cone was to the resistance on the convex surface as 1:4 to 1:5. The resistance on the base of a short cylinder was less than that on the base of a cone, though the areas were equal; also, on account of the different manner in which air acts on the posterior surfaces, the base of a hemisphere experienced less resistance than that of a cone, and the convex surface of a hemisphere less than that of a whole sphere of equal diameter.

The whirling-machine invented by Ferguson is a frame or box of wood, containing a wheel about 2 feet diameter, on the upper surface of which a table is placed. Spallanzani has examined the axes of all are in vertical positions, and, by strings passing over the wheel and pulleys, the latter are made to revolve on turning the wheel by means of a handle. The machine was intended to exhibit, in a popular manner, the principal effects of the centrifugal force, when bodies revolve in the circumferences of circles.

On the axe of each pulley there is fixed, at its middle point, a bar of wood in a horizontal position, and on this a small plate or cylinder of lead made to slide easily along two horizontal wires, extending from the centre to the extremity of the bar: a silk line attached to this plate passes under a small brass pulley near the centre of the bar, and over a similar pulley fixed in a brass frame, about 6 inches from the pulley above, to whose axe the bar is fixed, is made to revolve by turning the handle on the axe of the wheel; then, on placing such a weight on the carriage in the brass frame as will just allow the former weight to reede in consequence of the centrifugal force, a considerable distance, the carriage requires by the revolution, the weight in the frame, including that of its carriage, is to be considered as the equivalent of the centrifugal force.

For example, let the two pulleys be of equal diameters, and let the axis of each be horizontal, a plate attached with a sliding plate or carriage; then if a weight of 6 ounces, including the carriage, be placed at 3 inches from the centre of motion on one bar, and 2 ounces, including the carriage, on the other bar, at 9 inches from its centre of motion, the forces will be equal, the centripetal and the centrifugal forces will cause any equal weights on the carriages in the two brass frames to rise to the tops of those frames at the same instant. Here the velocities of rotation are represented by 9 and 3, and the weights by 6 and 2, so that the ratio compounded on the velocities and masses is one of equality; and this is considered as verifying the proposition that if bodies revolve in circular arcs, the centrifugal forces are equal when the products of the mass of each body and the square of the radii are equal. By joining the extremity of one of the pulleys twice as great as that of the other, so that when the bars are placed on the axles and are made to revolve by turning the wheel, the angular velocity of one may be half the angular velocity of the other: then if any equal weights, for example, be fixed on the carriages which slide on the two bars, at equal distances from the centres of motion; and if there be placed on the carriages, in the brass frames above those centres, weights, including those of the carriages, such that the weight above the larger pulley may be one-fourth of that which is above the smaller pulley; the centrifugal forces arising from the revolutions will allow these weights to be raised at the same instant, proving that both the revolving bodies are retained in circular orbits. Here the angular velocities of the revolving bodies are as 1 to 2, and the weights in the frames, which represent the centrifugal forces, are as 1 to 4; and the experiment shows that when equal bodies revolve in equal circular orbits, the centrifugal or centripetal forces are to one another as the squares of the angular velocities.

It is easy to understand that such experiments may be varied so as to exhibit all the phenomena of circular movements.

WHIRLPOOL, a place in a river, or in the sea, where, in consequence of obstructions from banks, rocks, or islands, the water is agitated by a revolving motion.

The agitation of the waters which is constantly observed near Messina, and which is usually designated the whirlpool of Charybdis, is now well known to be unaccompanied by any effect oceanic. If such vortexes might be absorbed, and is, rather, an incessant undulation of the water. The agitation is said to exist in several different places at the same time, within the circumferences of circles whose diameters, when the wind is moderate, do not exceed 100 feet; and is caused by the wind acting with the rapid current which sets towards the faro, or lighthouse, from the north during six hours, and from the south during the next six hours, and so on alternately; the changes taking place respectively with the rising and setting of the sun. The wind was rowed on the coast, and when the wind was light, experienced no danger, though the boat was much tossed by the waves: he was informed however that when the wind is high, the swelling of the waves is more violent and extensive, so that small vessels which are driven within the circle of danger by the waves breaking over them, and large ones may be driven on the Italian shore, where they are sometimes wrecked.

The sagging of the waves on the coast of Cape Frowd produces a noise which is said to resemble the barking of dogs; it is probable that these sounds gave rise to the fable that a female monster surrounded by ferocious dogs and wolves lay in wait to devour the mariners who might be wrecked on the coast.

The Maelstrom between the islands of Mosker and Varae on the coast of Norway appears to be of a similar nature: the tide there forms a current which runs with violence alternately from north to south, and in a contrary direction by the wind; and it is said that the waves, which have been described as so considerable, as to have created an agitation of the water, the sound of which is heard at sea to the distance of many leagues. At high and low water, in moderate weather, ships pass through the strait without danger; but during strong gales they keep near the banks in order to get into the current, in consequence of which they might founder among the waves, or be otherwise destroyed.

Whirlpools are produced among the Orkney Islands by the actions of winds and currents: but boats, it is said, pass over the spots in safety, a log of wood or a bottle of straw previously thrown into the water being sufficient to arrest its revolving motion.

The circular or spiral motion of the water, which constitutes a whirlpool or eddy in a river, is produced by the rotation of the banks or contractions of the bed; in consequence of which the current is opposed: and the contracting portion of the river, in order to find its way towards the middle: the ripples of water between the eddy current and the bank by which the waters from the upper part of the river are reflected, are called by the French the ripples, or a curneau de rives, the river having made its way towards the middle; the particles of water between the eddy current and the bank by which the waters from the upper part of the river are reflected, are called by the French, the current, ripples, or a curneau de rives, the river having made its way towards the middle; the particles of water between the eddy current and the bank by which the waters from the upper part of the river are reflected, are called by the French, the current, ripples, or a curneau de rives, the river having made its way towards the middle;
the contracted section becomes, by the laws of hydrodynamics, greater than that of the river above A B. Then the particles of water within the space a C D, rushing towards a c, in consequence of the pressure of the water of the river above, and of the momentum impressed on them in the contraction, are made to move in a direction parallel to a c, besides the current in the direction a c; and by the action of the forces in these directions the revolving motion takes place. Whirlpools are continually being formed in this manner, and are carried to some distance down the river both above and below.

Whirlpools may in like manner be formed at the same time, below B, on the opposite bank of the river, if this should have a similar form to the bank between A and C; or the stream a c e may be reflected from E, should there be a bank at the right place and situation. In the enlargement beyond, as shown in the diagram. Precisely in like manner are formed the whirlpools or eddies at the shoulders of the piers of a bridge, when the breadth of the river is so much contracted as to cause its surface above the bridge to be considerably higher than the surface below.

Under these whirlpools the bed of the river must evidently sustain less pressure than takes place on the parts about them; consequently the water under the bed, acting horizontally, may lift up the earth and stones, and thus undermine the piers; or it may blow up the piles driven for the formation of dams. By this cause the accidents which occur in hydraulic operations are frequently produced.

Inequalities in the depth of the bed of a river must evidently give rise to vertical whirlpools by the refluxion of the water from the ascending slopes; the particles then take an oblique direction upwards, so as to rise like a wave above the general surface: also a sudden depression of the bed will produce a vertical whirlpool in the lower part, nearly as the horizontal whirlpools before mentioned are supposed to have been formed.

WHIRLWIND is a violent movement of the atmosphere in a spiral direction about an axis, the latter having at the same time, as is now generally believed, a progressive motion, rectilinear or curvilinear, on the surface of the land or sea.

The tornadoes of North America and the coasts of Africa, as well as some in the sea of Chinn, have long been known as violent tempests in which the wind has a revolving motion about certain axes; but these terms are commonly applied to such storms as are of short duration and comparatively of small extent, the diameters of the vortices varying from a few hundred yards to one or two miles. It is now ascertained, by such evidence as leaves scarcely any doubt of the fact, that in all or most of the great storms which agitate the atmosphere the wind has a rotatory movement, and that the diameter of the circle with which the wind revolves is, in extent to several hundred miles: in great whirlwinds the axis appears to be either vertical or nearly so, but in those of small extent its inclination is often incomconsiderable, and it is sometimes parallel to the horizon.

As early as the middle of the seventeenth century the revolving motion of the wind, during the great hurricanes which take place in the West Indies, appears to have been noticed; and in a description of them, which was given at that time in the Philosophical Transactions, it is stated, that, after a cessation of the trade-winds, the storm begins from the north; that the wind afterwards goes round to the north-west and then to the south, the storm subsiding when the wind comes to the south-east; and in Colonel Capper's work on the 'Winds and Monsoons,' which was published in 1691, the gyration nature of the storms in the East Indian seas is inferred from the recorded changes in the directions of the wind during the storms of 1720 and 1770. Whirlwind storms appear however to have been then considered as local and temporary; and we see so far Mr. Redfield, of New York, that the direction of their motion is progressive as well as revolving. Mr. Franklin ascertained that the storm which he witnessed at Philadelphia in 1743, took a certain time to arrive at Boston, but he did not pursue the subject, and, from a mistaken notion of the distance between those cities, his opinion of the rate of movement is now known to be erroneous.

Though the fact of a revolving motion of the air is great storms may now be supposed to be the more properly understood. It is, however, generally admitted that the cause of the rotation is still obscure. Dr. Hare, of the University of Pennsylvania, who considers the rotatory movement as accidental, suggests that electrical discharges between the earth and clouds may cause an enlargement of the atmosphere, and to an extirpation of heat and a precipitation of aqueous vapours: partial rarefactions are thus supposed to be produced in the upper part of the atmosphere, in consequence of which cireums of air ascend from the surface of the earth to the atmosphere. It is observed that, when a storm in the horizon to supply the deficiency at the spots from where the air ascended. The agency of electricity is frequently manifest in storms; but, whatever be the cause, currents of air are frequently, as at the changes of the monsoons in the East Indies, may bear a certain direction towards one another, and thus rotatory motions in the atmosphere may be produced, exactly as eddies or whirlpools are formed in currents of water. [WHIRLPOLL.]

Mr. Redfield, in his 'Observations on Storms,' in the 'Transactions of the American Philosophical Society,' 1841, offers an opinion that generally during a gale there is, in the lower part of the atmosphere, a spiral motion inclining downwards and towards the centre; and in the higher regions a like spiral motion inclining upwards and towards the exterior. At great distance, and at great height, there is sometimes found a considerable area within which the winds are moderate and blow in various directions. These characters of a revolving storm appear to have been given by the manner in which the movement was observed during the hurricane which occurred in New Brunswick in June, 1835; when, about the centre, bodies of great weight were carried spirally upwards, and, on opposite sides of the storm's path, the trees were thrown in contrary directions. It is observed that, when a storm moves violently, the doors and windows of houses are often forced outwards, either from the centrifugal force caused by the revolving motion, or from the expansion of the air within. When a temporary rarefaction takes place on the exterior, there may be a considerable lowering of the barometer; and if a storm, in passing over a place, is in activity at a considerable altitude before it descends to the earth's surface.

That a whirlwind may have a progressive as well as a revolving motion may be easily understood if it be observed that, as the atmosphere in the tropical regions moves from east to west with respect to the surface of the land or sea, it may, after crossing the Atlantic and Pacific oceans, be arrested in its progress westward by the continental masses of America and Asia; and, from these towards the poles of the earth, the whirlwinds, formed by electricity or otherwise in the general current of air, will consequently be carried with the deflected branches into high northern and southern latitudes; and, generally, it is observed that the path and point of the deflected forces, the path of the axis of a revolving storm in either branch is a curve line like a segment of a circle or parabola. Sir John Herschel, at the meeting of the British Association in 1853, suggested that the whirlwinds of the United States and the north of Europe, were formed by the nearly circular and curved curves assumed by the paths of the storms on the coast of North America: the paths nearly coincide with the course of this stream, and the warmth of the water, by increasing the temperature of the atmosphere, and maintaining the storms which have their origin in a lower latitude.

It is evident that the velocity of the wind in a revolving storm must be the greatest and the least respectively at that point which is perpendicular to the path of axis, or for one side the direction of the revolving current combines with that
of the progressive motion of the storm, and on the other it is contrary to it. In other parts within the limits of the storm the direction and velocity of the wind must be compounded of the rotative and progressive motions; and it will happen frequently that a temporary calm is experienced at each point on the earth's surface at which the axis of the storm successively arrives.

The phenomena of tropical storms are not precisely such as they would be if the air had a simple movement of rotation; the particles of air, while revolving, are probably subject to manducatory motions in spiral curves, and local obstructions cause sudden and irregular changes in the direction of the wind, so that it appears sometimes to shift to different points all round the compass. Mr. Redfield states that, in small whirlwinds, the axis of rotation appears at times to describe great circles in looped curves about its mean place in the line of progressive motion; and the like gyrations probably take place in those of an extensive kind; but in order to simplify the explanation of the phenomena of whirlwinds, it is usual to assume that the particles of air revolve in the circumference of circles whose centres are in the axis; the latter having at the same time a movement of progression in a rectilinear or curvilinear direction. Now, if the plane of the paper represent the surface of the sea, and a line through the centres perpendicular to it, represent the axis of a whirlwind whose north and south diameter is N.S., and in which the particles of air are supposed to revolve (for example) in the direction indicated by the order of the letters N.W.S.E.; the progressive movement of the axis being also supposed to be from A₁ through N., or from south to north; then, since at N. a tangent to the circle lies due east and west, it is evident that a ship which would experience a wind blowing from the east when the centre of the storm is at A₁; and if the ship remain stationary, the wind will continue to blow from the same quarter till A₁ arrives at N., the tangents to the concentric circles supposed to be described by the particles being due east and west at the northern points of the circumferences as they successively arrive at N., and the wind in all the northern half of the storm revolving in the direction E.N.W.; but after this time, the wind blowing in the direction W.S.E. must be felt at N., as soon as M₁ arrives at N., and the remaining half of the storm has passed over that point. In like manner, if the axis of the storm were to move from A₁ towards W., a ship supposed to be stationary at the lat. point would feel the gale from the north till A₁ arrives at N.; after which, as soon as the particle by which it was produced leaves that point, the ship would experience a wind from the south. Again, if the axis were to move from A₁ towards A₂, that is, from south-west to north-east, for example, the direction of the whirlwind being as before according to the order of the letters N.W.S.E. and the ship supposed to remain stationary at some point, as M₁, till the storm has passed over it; then, the line of direction in which the points of the whirlwind successively overtake the ship being M₁M₂, parallel to A₁A₂ as the arcs M₁M₂, B₁B₂, &c. will represent the several directions in which the wind will successively be felt at the ship during the continuance of the storm. Thus the axis of the whirlwind being at A₂, the convex surface of the storm has just reached the ship, and the wind blows in the direction B₁M₂, or in the circumference of the circle whose centre is A₂, that is, nearly from the east-south-east. Next, the axis being at A₃, the point M₃ in the circumference of the circle whose radius is A₃M₃, is at M₁; and then, at the ship the wind is felt in the direction B₃M₃, or in the circumference whose radius is A₃M₃, or its equal A₄M₄, that is, nearly from the north-east; the axis at A₄, the point M₄ in the circumference whose radius is A₄M₄, is at M₁; and then at the ship the wind is felt in the direction B₄M₄, or in the circumference whose radius is A₄M₄, or its equal A₅M₅, that is, from the north-east.

In the American Journal of Science, vol. xx., it is shown that the storm which took place in September, 1837, in the Indies, and was described by Mr. Redfield, in the United States, in lat. 35° N., at day-light, September 3rd, when the wind blew from E.S.E.; on the same day, at 11 a.m., the storm commenced at Cape Henlopen, with the wind in the same quarter, but it afterwards shifted to the south, and blew with great violence. At New York the storm commenced at 5 p.m. from the east and north-east, the wind blowing with fury for which presents the most remarkable phenomena which it has been more attentively observed than those of the storms in any part of the world. The valuable publications of Mr. Redfield contain nearly all the details which have yet been collected concerning them, while the work of Colonel Reid, entitled 'An Attempt to develop the Causes of Storms,' contains almost all that is known of the whirlwinds in the southern hemisphere.
of August, 1837. Details of the circumstances attending it have been given at length, with a chart of its course, by Col. Reid, in his work on storms; and it appears that it was first felt in lat. 17° 30' N., about 400 miles eastward of Antigua, though it may have had its origin still farther east.

By the effects experienced at different points on the ocean, Col. Reid concludes that the centre or axis of the storm advanced at first from east to west nearly; and after moving in that direction about two days, it turned towards the north. When the storm had been abruptly turned from the land; and when the whirlwind ceased to be noticed, it was passing eastward across the Atlantic to the south of Newfoundland. On the 18th of August, a ship, named the Key, was blown off on a bar in the same vicinity; at that time a hurricane, named the Calypso, above three degrees northward of the Rawlin's, was thrown on her beam ends with the wind successively at N.W., W., and S.W.; and a ship, named the Sophia, situated about as far north-east of the Rawlin's, evidently eastward of the storm's centre, experienced the hurricane from the E.N.E., E., and S.E.

Previously to the temporary calm, the wind at the place of the Rawlin's had been N.E. by E. and N., and afterwards it suddenly changed to W.S.W. These circumstances sufficiently indicate that the whirlwind had then a progressive motion towards the north-west, and at the same time a rotation in the direction of the points N.W., S., E. On the 20th of August the wind at the point occupied by the Sophia appeared to veer, first to the north-west, and subsequently to the north; and since at this time the progressive movement of the hurricane had changed from a south-west to a north-east direction, the veering of the wind admits of being explained on the supposition that the Storm had then veered into the western semicircle of the whirlwind, while the latter, still revolving in the same direction, passed over her.

That independent whirlwind sometimes intersects with each other, and may be inferred from the circumstances attending the voyage of the Castries from St. Lucia to England in the same year (1837). This ship, between the 14th and 25th of August, sailed nearly from south to north on the chord of the arc described by the centre of the great hurricane; it was found on the 14th in about the 16th degree of north latitude, where the wind usually blows from the east, she felt a gale, which at first came from S.S.W., and afterwards changed to S.E., as if she had crossed the eastern side of a storm revolving in the direction of east. She then veered, like others, in the direction N.W., from east to west: this was in fact the said hurricane near the place where it was first observed. The Castries then sailed northward with fair weather till August 24th, when, in the 17th, and in long, became again over-taken by a whirlwind which passed over her. Now this could not have been the great hurricane before mentioned, since at that time the latter had passed beyond the spot towards the N.E., and the rotation at its southern extremity described about three-quarters of the circumference of a circle in the order just mentioned.

Mr. Field, of New York, Professor Dove, of Berlin, and Colonel Reid, in England, independently of each other, and nearly at the same time, ascertained, from the accounts of persons who had navigated the southern hemisphere, that in the whirlwind storms of those regions the rotation of the ships in the same place, in the direction N.W., E., S.W., or contrary to that in which the rotations are made in the North Atlantic; the axis of the storm having also a progressive motion from the equator obliquely towards the south pole. Such appears to have been the nature of the storm near the island of Rodriguez, between 1837, in which the Blenheim, the flag-ship of Sir Thomas Troubridge, founded: for it is observed by Col. Reid, that the Harrier, brig of war (one of the squadron), by scudding before the wind from the 1st to the 4th of February, which is the 4th of Feb.

And since the ships first received the wind from the south-east, it may be inferred that, by sailing south-west faster than the storm advanced, they actually overtook it at its south-east side. A like circumstance occurred to the ship Neptune during its voyage from Calcutta to the Cape in 1835.

From a rough account of the hurricane which burst at the Mauritius in March, 1818, it appears that the wind began early in the morning to blow from S.S.E. and S.; but in about an hour it changed to the east; and at daybreak it became N.N.E. and N., and when the storm had ceased, these circumstances indicate a rotation in the order N., E., S., W., about an axis passing a little way to the north of the island, from near east to south-west.

But the most remarkable storm which Colonel Reid has investigated is that which occurred in the Indian ocean, in March, 1809, when the fleet, under the convoy of the Chiltern and Terpsichore, suffered severely. The fleet, homeward bound from India, had got in lat. 21° south, when, on March 14, the hurricane became so violent that the ships were dispersed. By tracing the courses which they pursued, and also those of four ships which had sailed from the Cape to cruise near the Mauritius, Colonel Reid found that the general movement of the storm from the East Indies to the South Atlantic, in which the wind veered at each of the ships whose courses have been examined is capable of being represented by assuming that the rotation was, as in the preceding case, according to it, of 12th to 18th of March, the whole fleet appears to have been near the southern extremity of the vortex, and to have sailed in a direction parallel to the path of the axis. Seven of the ships, by lying to and keeping the 15th, and not having a storm, as they had been, in the southern branch of the line described by the axis, and crossed the northern extremity of the vortex as if it had moved south-eastward.

The vessel of Lieutenant M. B., being part of the fleet, by sailing eastward got, on the 15th, nearly to the centre of the vortex in the northern branch; on the 15th and 16th, this ship scudded before the wind, but it afterwards changed its course to S.E., and on the 18th it got out of the storm. The ships which lay nearest the vortex in the southern branch, kept the wind; they thus kept near the centre of the storm, where they must have founded.

In November of the same year, a hurricane which commenced in lat. 55° south, in the 25th of December, and appears to have had little progressive motion; all the ships which were exposed to it experienced a temporary calm in the midst of the storm, and on the afternoon of one day, November 21, the wind veered rapidly round the horizon in the storm which, in 1838, was on the south coast of Ireland, and proceeded from thence along the west coast. W. H. I.
Scotland, had all the characters of a whirling wind. It is stated by Colonel Reid that on the 14th of February, while at Cape Clear, the wind blew from S.E.; off Oporto the gale was from S.W.; at the same time, at the bottom of the Bay of Biscay, it was felt from S. and S.W.; and at the Shetland Islands, from the 16th to the 20th of February, the wind was from S.S.W. at Cadiz between the 7th and 12th of February the wind blew from S.W. and W.; and on the 10th, off Lisbon, there were heavy gales from S.W. to W.N.W. All these circumstances create a storm revolving in the order N., W., S., E., while its centre is frequently increased when the concave walls bends in its length, or when it is smaller at one extremity than at the other.

When the place is in the form of a dome, the undulations of the air, which are produced by a sound emitted from the concave surface of the dome, are, by continual deflections from every part of the concave surface, transmitted to a point in the base diametrically opposite to that from whence the sound proceeded; and there converges and concentrated sound to cause the perception of a sound many times louder than that which was emitted.

The whispering gallery in Gloucester Cathedral, which is described in Birch's 'History of the Royal Society,' vol. 1, is a passage leading from the aisle to the opposite, behind the east window of the choir: it is three feet wide, and about six feet and a half high, its whole length is about 75 feet, and its form on the plan is half an irregular octagon: the walls and ceiling are of freestone, and the latter, which is unoccupied, if two persons are placed, one at each end, near either wall, and one converses with the other in the lowest whisper, the words are distinctly heard as if the persons were close together.

The whispering gallery in St. Paul's Cathedral, London, is that which surrounds the base in the concave surface of the interior dome: here a person speaking in a whisper near the surface of the vault is heard distinctly by a person who stands also near the surface, even if a diameter, persons in any other part not being able to hear the sound. The like effect is said to take place on the exterior of the same dome if the persons speaking and hearing are at the opposite extremities of a diameter; the sounds are distinctly heard on the surface. For an account of the ancient whispering-place called the 'Ear of Dionysius' see SYRACUSE.

WHISTON, WILLIAM, was the son of Josiah Whiston, rector of Norton, near Twycross, in Leicestershire, and was born at that place, December 9, 1697. The materials for his Life are mostly contained in his singular autobiography, published in 1749; and from these the account given in the 'Biographia Britannica' is mostly taken. These memoirs, like others of the same kind, are not to be read without being preceded by the exercise of the mind in which there was much of vanity combined with unsuspected integrity. There never was a writer of his own life who laid his weaknesses more plainly before the reader, unless it were Boswell. Whiston's work was written by him in the last year of his life, and employed his son largely as an amanuensis till the age of seventeen. He was then sent as a pupil to Mr. Antrobus at Tarmouth, whose daughter he afterwards married. At the age of nineteen he was entered at Clare Hall in Cambridge, where he applied himself to the study of mathematics and the Cartesian philosophy. He took his degree in Lent, 1689-90, was elected a fellow of his college in the following June, and received his B.A. in 1693. In 1694 his health obliged him to give up his studies, and he was made chaplain to Dr. More, Bishop of Norwich. In this year he became acquainted with Newton, whose 'Principia' he had already studied. In 1696 he published his first work, the celebrated 'Theoricae Planetarum Hæresis,' which has been through six editions. His fancies on this subject, particularly his management of the comet for the production of the deluge, are well known: there was a joke against it, which was not without foundation, namely, that he had covered the whole of his head with black paper, having the figure of drawing it off again. In 1698 he got the living of Lowestoft in Suffolk, and by his subsequent marriage vacated his fellowship: during his tenure of this prebend he performed his duties there with great zeal and success.

But his connection with the university was soon revived, for in 1701 Newton made him his deputy in the duties of the Lucasian chair, and in 1703 resigned the chair itself, and procured Whiston to be appointed in his stead. He resided at Cambridge. In 1702 he published an edition of Tacitus.
Euclid, which was several times reprinted. He had also some clerical duties, obtained the character of an eminent preacher, and was fairly in the road to higher preferment, when his theological studies, in which he was most assiduous, brought about a gradual change in his opinions, which enabled his becoming an avowed enemy of the rejection of infant baptism to his system. His views on the matter were much influenced by a conviction which he obtained that the Apostolical Constitutions & Conferences, Apos, were not only genuine books, but equal if not superior to the epistles, and that he would violate the book of the Apocrypha. The change of his opinions soon appeared in his sermons and in his writings, which came out with great rapidity and were very numerous. The list was too long to quote, but he is always referred to as "Biographia Britannica." Very different varieties of doctrine were common enough at that time in the Church of England; and, if not made too public, views which were called heresies were connived at.

The bishop of Ely (Dr. Patrick), even when Whiston had gone so far as to omit part of the Litanies, and had consequently been cited, contrived to break up the court before the promoter made his appearance; and subsequently contented himself with desiring Whiston not to do the duties of a lecturership which he held at Cambridge, presenting the salary should be kept. But Whiston, whose whole life was one uncompromising act of maintenance of his own opinions, and defiance of his opponents, immediately resigned both office and salary. It is not always that a person who is not afraid of established dogmas will without an attempt to throw odium even upon his most reasonable acts. To what an extent this can be carried may be seen in the following instance:—A young candidate for a fellowship at Clare Hall, Dr. Cheke, was in the habit of spending long hours in the majority of the fellows were hard drinkers (and it seems that he was pretty nearly right), took to drinking by way of recommending himself. As the election drew near, he thought himself mistaken, and therefore applied to Whiston for his vote, confessing that he had been dined through policy, and promising sobriety in future. Whiston indignantly refused the request, telling the young man that he had sacrificed his integrity to his preferment. To this the writer of the Life in the 'Biographia Britannica' applies the following passage:—"Dr. Cheke's character had been much praised;"

In October, 1710, the storm burst upon the heretic. The heads of houses, after several hearings, to which they would not allow Whiston to bring a single friend, banished him from the University, after the usual offer of leave to recant, *which he did not* towards them. Both proceedings, as being done by the heads without a public trial in the vice-chancellor's court, were highly irregular, if we may trust the opinions given in sundry of the same body, but the College and Chancery confirmed them. Whiston was now thrown upon the world, but he had a small patrimony, and with this, his writings, his public lectures, and the occasional liberality of those who admired his unfailing character, particularly the cost had made of his life, of his sin, and law, he never was in want. His trials however were not yet over, and the heads of them will show how difficult, then as now, it was to define and prosecute heresy in the Church of England. The lower house of convocation censured his writings in 1711, but the censure happened to get mislaid before it was brought to the queen. Whiston, nothing daunted, published his 'Primitive Christianity' in November, whereupon the lower house applied to the upper house, but without effect. Further steps were thought of, and the justice was applied to information on the extent of the powers of convocation:—four were of opinion that there was no power to cite a heretic, but the rest were the other way. Still the controversy went on, and in 1719 in London delayed Whiston of heresy before the Dean's court of St. Paul's. The commissary of this court would not assume jurisdiction, but referred the matter to the Dean of the Arches, who in his turn objected to hear it except as an appeal. The decision fell upon the Chancellor, who appointed a court of Delegates, which decided that the Dean of the Arches ought to have heard the case, but proceeded to treat it as an appeal made to themselves. Whiston was accordingly cited, and appeared, but not upon the subjects of the matter, and after declaring him in contempt. This sort of thing happened so often, that we cannot but suspect the courts liked in such cases to take advantage of some party being a few minutes behind his time, and to escape the discussion. The lay delegates subsequently declared they would not proceed without a court of adjuncts to determine what heresy was. One of the delegates (a judge) affirmed that he would not take heresy on his shoulders nor on his conscience, and another kept whispering Whiston's counsel (Sir Peter King, afterwards lord chancellor), to move for a prohibition. Finally, in the court of adjuncts the Chief Justice, Sir Robert Walpole, disapproved of the whole, and said he would not allow the court to proceed. Accordingly, the proceedings were delayed till 1715, when all heresy was pardoned by an act of grace; and neither excommunication nor degradation ever followed. Whiston declares that the court of delegation met about once during the whole five years; he handed about his 'Proposals for finding out the Longitude at Sea by Signals' at the door of the court, and on one occasion presented each of his judges with a sheet, wet from the press, which they supposed was a petition, but which, on being fully displayed, bore the following title:—'The Cause of the Deluge demonstrated.' During the remainder of his life Whiston had no serious annoyance for his opinions. He was preached against and refused the communion by the clergy. But it continued. John Sacheverell, but he was never adverse from controversy, and would have been anything but pleased if he had not excited attention. He was also refused admission into the Royal Society. According to his account, Sloane and Halley asked him to join their scientific society, thinking the reason of this could not have been disapprobation of Whiston's opinions, for even supposing that Newton was not himself an Arian (which is a disputed point), his most particular friend Dr. Clarke was one, and we can hardly imagine [sic] that Sloane or Halley would have done the following if they supposed that he would not become a member, or that the Royal Society the opinions of his own most intimate associate. Whiston states as follows:—"Now if the reader desire to know the reason of Sir Isaac Newton's unwillingness to have me a member, he must take notice that in his making up my first Delegates, he took a discretionary power, and left the place, brought to me to be a candidate; and as his recommendation of me to the heads of colleges in Cambridge, made me his successor: so did I enjoy a large portion of his favour for twenty years together. But he then professed to be sincerely convinced of his error, and his proceedings were disallowed. If he had, that is, learned of him without contradicting him when I differed in opinion from him, he could not, in his old age, bear such contradiction, and so he was afraid of me the thirteenth years of his life. This and other remarks upon Newton's character passed from his conception till a few years ago, when the disclosures made to Flamsteed [FLAMSTEED] obliged many persons to adopt a somewhat lessened estimate of the social character of Oliver Goldsmith (who had however the sense to keep all signs of his foible out of his writings): but shallow he was not, though his learning was not of the deepest character. It is hardly to be imagined that Newton would have made a shallow person his deputy, or after trial in that capacity, suppose that he could not have seen that a long list of writings without seeing a good portion of shredness mixed up with his vanity. Some of his retorts deserve to be celebrated in the history of such things. Talking with Olive Goldsmith (who had however the sense to keep all signs of his foible out of his writings): but shallow he was not, though his learning was not of the deepest character. It is hardly to be imagined that Newton would have made a shallow person his deputy, or after trial in that capacity, suppose that he could not have seen that a long list of writings without seeing a good portion of shredness mixed up with his vanity. Some of his retorts deserve to be celebrated in the history of such things. was to be made to it." On another occasion (and this story does not come from Whiston himself, but from the 'Biographia Britannica,' in which the writer assures us it has it from undoubted authority), being in company with Pope, Addison, Walpole, Cranges, and others, they appealed to Whiston on the subject they were debating, namely, whether a bishop could not be excommunicated, and Whiston, without loss of his temper, replied thus: "I have been excommunicated, and I am lost." Whiston's reply may be imagined; on which Craggs said, 'It might do for a fortnight, but not longer.' To which Whiston replied: 'Mr. Secretary, did you ever try it for a fortnight? Craggs answered nothing, and Mr. Walpole said he could not answer. The story of telling Queen Caroline, at her request, one of her faults, talking during public worship, and refusing to tell another till she had amended that one, is well known. Such readiness to be excommunicated at all times, supposed, was invaluable to a person in Whiston's position.

There are various circumstances of Whiston's life which it is not necessary to do more than name: his formation of a religious society which met at his own house—his various publications, oral and printed—his multiharifious speculations on prophecy, particularly his decision that the Jews were to be restored and the millennium to commence in 1786; his speculations on finding the longitude, whether by attempting to moor fixed vessels in the sea (which he attempted in vain), by a clock invented by him, or by Jupiter's satellites, &c; his survey of the coasts of England by subscription, which produced a useful chart, &c. He died August 22, 1752, in London, at the age of eighty. A book has not yet allotted his efforts for the diffusion of his opinions, in which he forsook the subject, on account of his character for courageously consistent. He left several children, one of whom, John Whiston, made a fortune as a bookseller, and published many of his father's later works.

Whiston left, which appeared with a great deal of care, fifty-nine in number. Only one has lasted, the translation of Josephus, published in 1737. This book has been reprinted a great many times. The Puritans have always had a sect lined down from them, who made it a point to show that the English were never a divided people (in this sect subdivides into two, the second books of the subdivisions being Bunyan's 'Pilgrim's Progress' and Whiston's 'Josephus.' Of this translation the general opinion, as a translation, is favourable.

If what the Edinburgh Review asserts be correct, namely, that the recent discovery of Milton's Ariasianism has diminished the sale of 'Paradise Lost,' we may almost wonder that Whiston's 'Josephus' gained so firm a footing among sects of the most rigorous orthodoxy.

To what has been said of the character of Whiston, we may add that his spirit, though benevolent, was so strongly suspect, not much inclined to toleration. His ideas of ecclesiastical discipline and authority were so high, that we have heard him publish a statement to the effect of a church a bishop who had led his clergy the lives of slaves, and been far from showing towards heretics the in- disposition to prosecute which Hopper, Burnet, and others showed towards him. Almost his first act upon leaving Cambridge after his banishment was to set a parish priest upon making inquiries with reference to refusing the communion to a lady who was suspected of not being married to the man whose name she bore, though the matter was so mean, so vain, to regard less, and came to Whiston's knowledge as a matter at the house, to which it was ad- duced by his respectable friend Dr. Clarke. His perfect sim- plicity is displayed in his manner of telling this story ('Memoirs,' p. 183) and many others; as also in the otherwise quaint character of his epigrams, and in his letters to the per- sons of others. He seems not to have had the smallest idea of the proprieties of private intercourse; perhaps his incapability of concealing his own foibles belonged to a temperament which also prevented his seeing what he was doing with a clear eye. His reasoning was always perfectly clear, and his memory perfect; but his logic was weak. The supposed importance of what he had done or was to do, than to his own power as the doer of it. He does not hold him- self up as a great scholar, or divine, or mathematician. When Cotes, a very young man, was candidate for the Plumian professorship of mathematics in Cambridge, to which he was elected, the election was managed thus, according to Whiston: 'I was the only professor of mathematics directly concerned in the choice, so my determination naturally had its weight among the rest of the electors, and that I pretended myself to be not much inferior in mathematics to the other candidate's master, Dr. Harris, but confessed that I was but a child to Mr. Cotes: so the votes were unanimous for him.' Whiston seems to have been more vain of his sincerity than of anything else: and certainly the number is not small of those who would be much the better even of a double portion of his weaknesses, if they could there too be honest. His fearlessness, and honesty. To none more does this remark apply than to a certain dignified clergyman of his own day, whose writings were a disgrace to his profession, and who in a letter written between him and his correspondent, said the epigram 'wicked' to the subject of it, accompanied by expressions of contempt which the lowest of our day do not venture aloud in the street without first looking to see that no policeman is in hearing. What would have been the tone of the next common phrase, 'the decent part of society,' in the age in which Swift was allowed to cast a stone at Whiston?

WHITAKER, REV. JOHN, was born at Manchester about 1736, and studied at Oxford, where he took his de- gree of M.A. in 1758, and B.D. in 1767; he was Fellow of Corpus Christi College. In Rees's 'Register of Living Authors of Great Britain,' 8vo., Berlin, 1791, there is attributed to Whitaker a 'Survey of the Doctrine and Arguments of St. Peter's Epistle,' with a parenthetical notice of 'the Montgomery' ('Survey,' published in 1751; by this it is supposed Whitaker's first publication appears to have been the first volume, in 4to., of 'The History of Manchester,' which appeared in 1771, and which was followed by a second volume in 1773; the third appeared in 1834, in 2 vols. 8vo., in 1773. Meanwhile also he had published, in an 8vo. volume, in 1772, his 'Genuine History of the Britons asserted,' in answer to James Macpherson's 'Introduction to the History of Great Britain and Ireland,' which appeared in 1763, in 4to. and was accompanied by a preface, in 1764, by Whiston. It is said that Macpherson's 'Introduction,' It is supposed that the Macphersons nor Whitaker threw very much light upon the subject, and that the speculations of both have been superseded and made quite valueless by subsequent investigations.

In November, 1773, Whitaker was appointed morning preacher of Berkeley Chapel, London; but the person, Mr. Hughes, who had given him the situation, thinking proper to remove him in about two months after, Whitaker was removed from the last place he held. He was for a time a librarian of the Bodleian Library, and was also, Mr. Whitaker and Mr. Hughes, &c., in which, his bi- graphier in Chalmers (a personal acquaintance) tells us, 'he expressed himself so indirectly that his "Case" was considered as a libel by the Court of King's Bench.' This would seem to mean that the publication had been made the subject of an indictment or an action. Having soon after this given substantial proof of his scrupulous ortho- doxy by refusing a living in the church which was offered to him by a Unitarian patron, he remained with nothing but his fellowship till 1776, when he succeeded, on the presentation of his college, to the valuable rectory of Ruan-Langborne in Cornwall. Taking up his residence here, he became involved in a contest with his parishioners, whose understanding was quite different from his own, and feared the result would be to a greater extent than he had hitherto been under suspicion. He was an animated and impressive preacher, and in all respects an attentive and zealous clergyman. His principal publications after this were, an octavo volume of 'Remains upon Divine Judgments,' published in 1783; 'Mary Queen of Scots vindicated,' in 3 vols. 8vo., 1787, of which a second edition, much enlarged, appeared in 1788, in the same number of volumes, in 1790; Gibbon's 'His- tory of the Decline and Fall of the Roman Empire Re- searched,' 8vo., London, 1791; 'The Course of Hannibal over the...
Euclid, which was several times reprinted. He had also some clerical duties, obtained the character of an eminent preacher, and was highly esteemed in the road to higher preferment, when his theological studies, in which he was noted and distinguished, brought about a gradual change in his opinions, which ended in his becoming an Arian; he finally added the rejection of infant baptism to his system. His views on the matter were much influenced by a conviction which he obtained that the Apostolic Constitutions, Assemblies, were not only genuine books, but even if not superior in authority to any of the books of the New Testament. The change of his opinions soon appeared in his sermons and in his writings, which came out with great rapidity and were very numerous. He long for the 'Biographia Britannica,' the varieties of doctrine were common enough in the Church of England; and the views which were called hereesy.

The bishop of Ely (Dr. Patrick), even gone so far as to omit part of the doctrine of the Trinity, to the great life of his exposition; his sentiments must do the duties of a lestrship.

Thomas Dugdale, LL.D., the heir of Dr. William Dugdale, bishop of Salisbury, and one of the eminent clerical dignitaries of the reign of Edward IV.

He was in his younger years apprenticed to the profession of the law, but after the death of his father, in 1782, he contrived to buy the estate of Holme, in Yorkshire, and in 1791, he took the degree of L.L.D. in the University of Oxford. He was inducted to the archbishop of Canterbury, and in 1818, he was created a bishop in the Church of England.

In the year 1797, probably on his return from his travels in the continent, he took the degree of L.L.D. in the University of Oxford, and was inducted to the archbishop of Canterbury, and in 1818, he was created a bishop in the Church of England.

Though the public spirit of the times, and the sedition of the day, were against his views, the bishop of Ely, in his capacity as a bishop, was enabled to maintain his principles, and to continue his support of the doctrines of the Established Church, and to promote the welfare of the clergy and the people, by his influence and example.

Mr. Whitbread's publications consist of a number of single pieces, some of which are of the following antiquarian works:—A History of the Counties of Lancaster and York, 4to, 1806, reprinted, with additions and corrections, in 1806; History of the Deeney of Craven, 4to, 1818; account, in Latin, of the life and manners of the Romans in Britain, in the reign of Trajan, A.D. 200; The Lives of the Poets, 4to, 1812; The Visions of Poets Ploughman, 4to, 1810; a collection of the lives of the poets, from the earliest times to the present, with some remarks on the life of Mr. Dryden. The History of English Poetry, ii. 480-510; a collection of the lives of the poets, from the earliest times to the present, with some remarks on the life of Mr. Dryden. The History of the Poets, 4to, 1816; Loidia and Elmente, or a Panegyric of the brave and generous King of the Britons, in the reign of Edward the Confessor. The History of the Britons, 4to, 1816; Loidia and Elmente, or a Panegyric of the brave and generous King of the Britons, in the reign of Edward the Confessor. The History of the Poets, 4to, 1818; Loidia and Elmente, or a Panegyric of the brave and generous King of the Britons, in the reign of Edward the Confessor.

Mr. Whitbread's political career was the impeachment of Lord Melville, which he conducted. He was a warm advocate of popular education—a man of deep religious impressions. There was however nothing sectarian or bigoted in his religion, as may be inferred from the active part he took in the formation of the University of London, and his support of the Oxford Movement, and his opposition to the Catholic Emancipation Bill.
In 1833 an act was passed for better paving, cleansing, lighting, watching, and improving the town of Whitby; and an act for repairing and building of houses has been handed down in the above act. In 1833 an act was passed for making a railway from Whitby to Pickering, which is distant about 20 miles south by west. This railway was opened in May, 1836, for passengers and general traffic; it has only one track, and is worked by horses and two inclined planes. A branch railway goes to the freestone-quarries, which are about three miles from Whitby.

The population of Whitby, in 1821, was 8697; in 1831 it had fallen to 8248; and the number of houses was 1672. The population of Whitby, including the townships of Ruswarp, Hawsker, and Staithes, was, in 1831, 10,999; and in 1841 it was 9862.

Whitby is an ancient place; it seems to have arisen originally from the neighbourhood of an abbey founded by Oswy, king of Northumberland, in 867; but both abbey and town were utterly destroyed by the Danes, and lay in ruins till after the Norman conquest, when the town was rebuilt. It became a considerable fishing town, in which it stated continued several centuries. It did not rise in commercial importance till towards the end of the reign of Queen Elizabeth, when the working of the alumines in the neighbourhood was greatly extended, the harbour was improved, and ship-building was carried on. Alum was exported to France and other parts of the continent. During the late were numerous docks were in employ in ship-building and repairing, and manufactures of sailcloth, ropes, and other necessaries for shipping were carried on to a great extent. In 1819 twelve ships were employed in the whale-fisheries. The export of alum to the continent has since declined, and it is now sent chiefly to London and other British ports. The port has nearly if not entirely ceased to employ its ships in the whale-fisheries. The manufacture of sailcloth has diminished, and only three or four of the docks are now used. The foreign exports are considerable, that are timber, and hemp and flax from the Baltic. The chief sent coastwise is freestone from the quarries in the neighbourhood.

Whitby is still a very considerable seaport. There are only seven in England which exceed it in the number of registered ships (London, 2465 ships, 598,554 tons; Newcastle, 1143 ships, 229,571 tons; Liverpool, 1097 ships, 307,622 tons; Sunderland, 803 ships, 174,502 tons; Whitsone, 341 ships, 55,501 tons; Hull, 223 ships, 67,796 tons; and Yarmouth, 315 ships, 34,676 tons). According to a parliamentary return, dated March 23, 1842, the number of registered vessels above 50 tons was 291, the burthen of which was estimated at 47,507 tons; and, according to another return, the gross receipts for the year 1842 was £6654. 18s. 7d., 3914 14s. 10d. having been remitted to the receiver-general after payment of expenses.

(Continued from next page.)
necessary conditions of communion.' The book (which was anonymous, but the authorship of which appears to have been soon discovered) was immediately attacked with great fury from various quarters: the University of Oxford, in a congregation held on the 21st of July, condemned it; and the burn was put out by the marshal of the Schools Quadrangle; and at length Whitby, on the requisition of his diocesan and patron, Bishop Ward, signed on the 9th of October a strong expression of his sorrow and repentance for having 'through want of prudence and duty' caused 'error' to spread. Dr. Whet and Whitby published, and his distinct retraction of its two main principles—that it is not lawful for superiors to impose anything in the worship of God not antecedently necessary, and that the duty of not offending a weak brother is inconsistent with a man's right of deciding indifferent things—both of which he now professed to have discovered to be false, erroneous, and schismatical. The same year he also published a second part of the 'Protestant Reconciler,' earnestly pressing the Dissenting clergy to join in full communion with the Church of England, and answering all the objections of non-conformists against the lawfulness of their submission unto the rites and constitution of that church.

To publishing a Latin compendium of ethics, 'Ethics Compendium in usum academie juventutis,' 8vo., Oxon., 1694, returned to his old subject, the errors of popery, and published 'A Treatise in justification of the Latin Service in the Church of Rome,' 4to., Lon., 1697; a treatise in the Roman Calendar,' 4to., Lon., 1697; a treatise against the worship of images; 'A Demonstration that the Church of Rome and her Councils have erred,' 4to., Lon., 1688, on communion in one kind; and 'Treatise of Traditions,' Part I., 4to., Lon., 1689; Part II., 4to., Lon., 1690.

He next came forward in defence of the Revolution, in two tracts: the first entitled 'Considerations humbly offered for taking the Oath of Allegiance to King William and Queen Mary,' 4to., Lon., 1690; and the second, 'Historical Account of some things relating to the Nature of the English Government, &c.,' 4to., Lon., 1690. These were followed by 'A Discourse confirming the Truth and Certainty of the Christian Faith, from the Extraordinary Gifts of the Holy Ghost vouchsafed to the Church from the Year 1551; a treatise in Latin against Arianism and Socinianism,' 'Tractatus de Vera Christi DEITIS,' 4to., Ox., 1691; and 'A Discourse of the Love of God,' 8vo., Lon., 1697.

In 1703 appeared, in two volumes folio, his principal work, 'The Peace and Concord of the Church and State,' 8vo. This has been often reprinted, and is still held in much esteem by the adherents of the Armenian system of doctrine. The best edition is that of 1706, in 2 vols. fol.; and that was reprinted so recently as 1825, in one volume, royal 4to. In connection with it afterward published 'A Discourse of the Necessity and Usefulness of the Christian Revelation, by reason of the Corruptions of the Principles of Natural Religion among Jews and Heathens,' 8vo., Lon., 1697; 'An Account of the Opinions of Mr. Dodwell, &c.,' 8vo., Lond., 1707; 'A Discourse concerning the True Import of the words Election and Reproduction,' 8vo., Lond., 1710 (commonly called 'Whitby on the Five Points,' and often reprinted; the best edition is that of 1723); there was one of so late a date as 1817; 'Four Discourses' (on Election and Reproduction), 8vo., Lond., 1710; a treatise against the doctrine of Original Sin in Latin, 'Tractatus de Imputatione Divina Possess Adami Posteris ejus, &c.,' 8vo., Lond., 1711. While he was editing a Catholic university having been all of that persuasion; and, as he states himself in a preface to one of the above tracts, his own investigations and reflections had gradually brought him to a different opinion.

But his views afterwards underwent a still further change. Dr. Clarke's 'Scripture Doctrine of the Trinity,' which appeared in 1712, made him a convert to Arianism, and he afterwards published the following tracts in defence of this doctrine: 'Disquisition de Animae Predestinatione' (against the authority of the Fathers in the controversies about the Trinity), 8vo., 1714; 'A Discourse showing the Expositions which the Ante-Nicene Fathers have given are more agreeable to the Interpretation of the New Testament,' &c., 8vo., Lond., 1714; 'A True Account and Confutation of the Doctrine of the Religions,' 8vo., Lond., 1616; and a dissertation in Latin, on the difficulties which attend the study of the doctrine of the Trinity, under the title of 'Disquisition Modestae in Bulli Defensionem Fidelis Nienae,' 8vo., 1723. This last tract involved him in a controversy with the great Trinitarian champion, Dr. Waterland. Whitby defended himself in two additional pamphlets, published this same year, and retained his Arian principles to the end of his life, as appears from his posthumous work entitled 'Terpea foedera,' or the Last Confutation, containing several passages in his Commentary of the New Testament; to which are added Five Discourses, published by his express order; 8vo., Lond., 1728.

Meanwhile he had published another tract on the Romish Pope, 'Dei Panarum Necessum; the Discription of the Breaden God, &c.,' 8vo., Lond., 1716; and he also took part in the Bangestine controversy, by two pamphlets in defence of Bishop Hobson, to which he added, 'A Letter to the Bishop of Bangor,' 8vo., Lond., 1717; the second, 'A Defence of the Propositions contained in the Lord Bishop of Bangor's Sermon,' 8vo., Lond., 1718.

To this long list are still to be added six single sermons and a Dissertation, all different times. 'Thirty-three Sermons upon the Attributes of God,' 2 vols. 8vo., Lond., 1710; 'Sermons on Several Occasions,' 8vo., Lond., 1720; 'Twelve Sermons preached at the Cathedral Church of Stram,' 8vo., Lond., 1728; besides an anonymous work, 'An Account of the Reviews, and the True Meaning of the Reviews,' 8vo., Lond., 1711—a severe attack on Bishop Beveridge—of which he is supposed to be the author.

WHITE RIVER. [Mississippi River.]

WHITE SEA, a large gulf of the Arctic Ocean, which enters deeply into the northern parts of European Russia, and is situated between the 64th and 68th degree of latitude. The surface of the sea, on account of the number of large islands, is more extensive than any of the open seas, and nearly the shape of a semicircle, whose opening is directed towards the north-west, and which is separated from the open sea by a large peninsula, which takes its orient name from the town of Naryn, on the north shore. The entrance to the White Sea is between Kamsa Nosa, on the peninsula, or rather island, of Komanska Zemlia, which lies to the east, and Swatska Zemlia, a projecting cape of the peninsula of Kolva. These two places are about 250 miles distant from each other, and the innermost part of the sea is gradually grows narrower, and where it turns to the south-west it is hardly more than 40 miles wide. That portion of it which lies east and west is nearly twice as wide, and extends towards the south into two large gulfs, the Dwina, or Gulf of the Dwina, and the Onega, or Gulf of the Onega; both bays have received their names from the rivers which fall into their most south-eastern recesses. West of the Onega Gube the White Sea terminates, which is about 250 miles long, but has only a mean width of 25 miles and less to the north-west. It is called Kandalakska Guba, or the Gulf of Kandalaksha, from a small place of that name which lies near its innermost recess. The area of this sea is said to be something more than 20,000 square miles. The White Sea is so far favourable to navigation, that it has a considerable depth of water, and yet within soundings, with the exception of a sandbank which lies before the mouth of the Dwina, and occupies the greatest part of the Dwina Gube, and lies entirely within the eastern shore within about a mile, and remains about three miles distant from the southern shore. Large vessels therefore must keep near the shore, which is generally rocky and of moderate height, but may be safely approached as far as the depth is seldom less than 3 fathoms; and lies soon after the entrance of the river Dwina, which at low-water has only 12½ feet of water, and at high-water from 14 to 15 feet; at spring-tides it rises to 17 feet. But the sea is frequently covered with ice, which are thick at times from the shore, but much less so as one approaches.
which circumstance renders them less dangerous to shipping. The navigation generally lasts six months, as the ice in the Dvina begins to appear at the end of October, and before the beginning of May the river cannot safely be entered by vessels. Some account of the trade of this sea is found under Amsterdam, vol. iii., p. 2377.

Fish is more abundant in the White Sea than in any of the closed seas of Europe. Seals are very frequently met with on the shores. The white fish, as it is called by the whalers of Spitzbergen, or the beluga, is of very small size, and great value. In a barrel of salable oil, and is met with in large shoals. Cod is taken in great quantities along the coasts of the peninsula of Kol. Herring are as numerous along the coast of Nor- way as in the Baltic. The diseases is a chief concomitant of the summer, the small lakes along the coast, and is much esteemed for its flavour. It appears that the White Sea is the most western part of the Arctic Ocean where this fish is found. Other kinds of fish which abound are the Gadar mandulans, Gadus callarias, and the flat fish which is called Pleronecestes glacialis. But the fishery carried on by the population on the shores of the White Sea is not limited to that sea. From Archangel, Messen, and Onega many vessels are annually sent out to fish in Spitsbergen and Nova Zembla, where they take whales, the nar- whal, the Physter mareocephalis, or white whale, seals, and the walrus. The walrus is called in the Russian language morph, from the English morse is derived, as the teeth which formed the points of the animal were first brought from England to the White Sea.

The whole eastern coast of America, from the mouth of the St. Lawrence river to the Strait of Magalufons, had been explored before the existence of Europe. It was known to the seafarings of Europe. It appears that before 1553 the farthest point known in these parts was Vardeheus in Norway. In that year however Richard Chancellor, with his ship belonging to the squam- beri, making a voyage to the northward, discovered a northern passage to Nyiarvalen, and, been from the north-east passage to Catala, or China, arrived at St. Nikolaus, not far from the present town of Arch- angel, and by this voyage, and the negotiations which followed, it was opened to English commerce, and with Archangel. Towards the end of the century it became a steady port, and the vessels employed were more numerous, which allows the English to have over sea-faring nations had been taken from them, and their profits were greatly reduced. After the foundation of St. Petersburg the commerce of Russia was diverted from the White Sea to the Baltic. And this loss was a short time completely effectuated by the energetic measures of Peter the Great. During the whole of the last century the commerce of Archangel was a languishing state, so that between 1751 and 1763 not more than 40 vessels on an average visited the port of the capital. It had diminished to a third, and in 1763 had annually amounted to 150. The empress Cath- erine II. did little to raise it, but Paul I. and Alexander took off the restrictions under which Peter had laid its commerce, and since the beginning of this century it has continued to increase rapidly.

WHITE SWELLING, a disease of the joints, so called on account of the inflammation which affects the skin. Under this term are included nearly all those diseases of the joints which are the result of chronic inflammation in the bones, cartilages, or membranes constituting the joint. These inflammations are constantly attended with swelling, which is caused by the pressure of the fingers, and thus leading to the impression that the bone is swollen and diseased; or it may be elastic, and yielding to pressure; or so soft as to produce the impression of the presence of fluid. Sometimes these swellings are attended with no pain, at other times pain is one of the earliest symptoms, and is constantly increased by the motion of the limb. In some cases the motions of the joint are but little impeded, while in others they are entirely destroyed. These general symptoms however admit of distinction, and seve- ral forms of white swelling, which can be traced to the joint as their seat. Amongst older writers these diseases have been described under the names of spina ventosa, fungus articulari, lymphatic tumor, and other names. A common division of the pain is derived from the felt fluid into the joint, and is less serousious, according as they were supposed to have their origin in a chronic or serousious state of the system. The more active were referred to the former and the chronic to the latter. Many other distinctions are founded more upon the age, temperament, and constitution of the patient, than upon essential differences of the disease. The following are the diseases of the joints which are generally denominated white swellings.

1. Inflammation of the Synovial Membrane.—This disease may be either acute or chronic. When acute, the skin is generally red, and the joint very painful and tender. It commences with pain at one particular spot, and in a day or two after, swelling takes place. The swelling may be felt at first to undulate, from the effusion of fluid into the synovial membrane; but the symptoms lessen from advances, from the thickening of the membranes and also from the effusion of lymph. The swelling always assumes the form and direction of the synovial membranes. In a chronic case, the pain begins at one point or assumes the chronic form. When the inflammation is acute from the beginning, the pain and tenderness are much less, so that the patient is able to walk about without much difficulty. There is little or no fever, the skin retains its general colour, the joint shows no swelling, the synovial membranes and the seat of the articular surface of the joint are not altered, and from the effusion of fluid into the joint, the fluids are rendered worse by exposure to cold and exertion. In these cases, although the swollen fluid may at length become absorbed, the synovial membrane remains thickened, and swelling and stiffness of the joint are the consequence, constituting a very chronic form of white swelling. The causes of this disease are both constitutional and local. It may arise as an effect of phlebitis, gout, rheumatism, syphilis, or mercury; or it may be produced by sprains, contusions, wounds, dislocations, or frac- tures of the heads of bones.

The treatment of this disease must vary according as it is acute or chronic, or dependent on local or constitutional causes. In the acute and local form of the disease perfect quiet of the patient, and the part should be covered with a dressing and leeches to the part should be had recourse to, with some purgatives and diaphoretics. When the skin is tense, fomentations and poultice may be used; but where not, cold lotions will be best. In the early stage of the chronic form leeches and cold lotions to the part, may be applied and perfect quietude enjoined. In the latter stages counter- irritants may be used, such as blister, the savine cerae, ointment of tartarised antimony, &c. When persons are well enough to move about, the joint should be kept from movement by strapping it with soap-platter, or covering it with a bandage or a cap of leather or other material made to fit tight. For the removal of the stiffness, cham- pooning, the vapour-bath, or friction with the hand, may be employed. When the inflammation arises from rheumatism or syphilis, the treatment should be the same as for those diseases.

2. Pulpous Thickening of the Synovial Membrane.—This disease generally occurs in young persons between the age of sixteen and fifty, and is apt to affect the knee-joint. There is not much pain in the joint, but swelling and rigidity come on slowly. The joint on being touched appears to have fluid in it. This disease goes on sometimes for years, till at last it destroys the joint; and unless the limb is amputated, the synovial membrane can never be removed. The disease consists in a total disorganization of the synovial membrane, which is converted into a brownish or lightish brown pulpous substance, varying from a quarter of an inch to half an inch in thickness. In its advanced stages the cartilages, bone, and ligaments of the joint become implicated in the disease.

Vol. XVIII.—2 X
The well-marked cases of this disease must be looked upon as incurable, and only amputation will give a chance of relief. A systolic and subclavian pulse is the only sign of the disease to offer success is perfect quietude of the joint, which may be secured by pasteboard or other splints, or by soap-plaster. The general health should be attended to, and local applications made according to the symptoms. Inflammation should be subdued by leeches, and gentle counter-irritants may be kept constantly applied.

3. Ulceration of the Cartilages.—This disease occurs chiefly in children or adults under the middle age. It is frequently a consequence of the preceding diseases, but often aseptic, although involving the whole joint. The joint in which it is most frequently seen is the hip, producing the greater amount of the diseases known by the name of hip-joint disease. When it occurs in the knee, it is called by the inflammation of the synovial membrane by the pain at the commencement of the disease being slight, and its going on in increasing intensity. The pain is also present sometimes four or five weeks before any swelling is perceived. The swelling, when it occurs, is generally found on the calf of the limb outside of the joint, and often appears much larger than it really is, from the previous wasting of the leg from want of use. In many cases an effusion takes place into the synovial membrane and increases the swelling. In the process the disease affects both synovial concretions and synovial membrane and the surrounding membrane. As the cartilaginous tissue is renewed with difficulty, the most favourable termination of this disease is generally attended with ankylosis of the joint. When the disease affects a joint which moves the limb affects the diseased cartilage. The limb may be placed in splints, or bandaged up with soap-plaster, or perfect quietude of the joint may be secured by a plaster of Paris. The advantage of being employed to make applications to the part affected. Where the joint is hot, cold lotions and leeches may be applied; but where it is cool, counter-irritants, blisters, issues, moxas, antimonial ointment, or croton oil may be employed. For the swelling and rigidity which so constantly remain, relief may be sought in the douche, fomenting, or friction with the hand.

4. Scrofulous Disease of the Joints, beginning in the Bones. — Hall, at his death, was ambitious to involve the bones, and this on account of the apparent enlargement of the bones of the affected joint. That this is not the case, the existence of the above forms of disease proves, but even the fact on which the supposition was founded in the scrofulous cases. So far from the bones being enlarged in these cases, there are only a very few on record in which dissection has shown the bones to be enlarged. The bones have been supposed to be swollen from the hardness of the bone and its size: but the former arises from the softness of the bone, and the latter will be greater by contrast with the wasting diseased limb. But the bones are subject to disease which begins in their cancellous texture. The phosphate of lime is removed from them, or deposited in less quantity, and a yellow caseous substance is secreted in its place. The heads of the bones are altogether weakened and softened, and deposits of bony matter of an irregular form are found on their outside. Whilst this change is going on the bone becomes pain; then swelling; and it most commonly attacks, swells; the motions of the joint are affected, and it becomes more or less contracted, so as to prevent it being straightened. In the course of time matter is formed in the cavity, and makes its way outward, forming a swelling through the abscess forms on the outside of the joint. Sometimes sinuses occur, and run to a considerable extent from the joint under the fascia, or between it and the skin.

The condition of a limb is generally connected with a scrofulous constitution; and the scrofulous disposition, the more difficult will the disease be to treat. However, whatever may be the state of the constitution, this must be attended to primarily in the treatment of these cases. Under the general principles of which such cases should be treated. The local treatment must be the same for other cases of white swelling. Quietude of the joint should be secured on some of the plans previously proposed, and as there is a constant tendency to ankylosis, care should be taken if possible that the ankylosis occurs in a position most suitable for the use of the limb. Counter-irritants will be found of great utility in these cases, such as blisters, antimonial ointment, and croton oil. Care however must be taken that they are not employed whilst there is a tendency to inflammatory action; and, on the other hand, the means that are employed, such as leeches, cold lotions, &c., for an increased activity of the part, should be immediately abandoned when that activity ceases. When the morbid process has been arrested, fomenting, friction, and pouring water on the part from a height should be the only means of treatment for a short period: for the purpose of strengthening it. The abscesses which form in these cases should be opened early; if left to themselves, they often leave ulcerations which are difficult to heal.

(From Cooper's Practice of Surgery; Surgical Dictionary; Brodie, Pathological and Surgical Observations on Diseases of the Joints.)

WHITE THORN, or HAWTHORN. [Crataegus.] WHITE, ROBERT, an English line and mezzotint engraver, born in London, about the middle of the 17th century, He learnt drawing and etching of David Loggan, for whom he drew and engraved many buildings. He has engraved a large collection of English portraits, many of which were drawn by himself from the life in lead-pencil upon vellum. He drew also several interpretations of the heads, leaving little for posterity to be seen in engraved in Sandrart's 'Deutsche Academie,' &c. Sir Godfrey painted White's portrait in return.

While engraved the first Oxford Almanac in 1674. He was busily employed for forty years, and he had amassed about £5,000. He was not educated. He had indigent at last: in 1704 a plague sufferer, it is the Poulter, who purchased his plates, made a fortune in a short time. Walpole has given a list of about two hundred and eighty of his plates, in which he has placed the following observation: 'As the man exceeded Robert White in the multiplicity of English heads, it may be difficult to give a complete catalogue of them.' Yet as my author (Vertue) had formed a long list, it would be the best service curators if I refused to transcribe it.'

GEORGE WHITE, the son of Robert White, was also a clever mezzotint engraver and a painter. He was instructed by his father, and he completed some plates left unfinished by his father. He continued the mezzotint, and the following heads in this style are very good:—the Duke of Ormond, Lord Clarendon, Sylvester Petyt, Sir Richard Blackmore, Colonel Blood, who stole the crown, and the notorious Jack Sheppard, after Sr C. pressed, and painted by John Smibert. (Catalogue of Engravers, Strutt, Dictionary of Engravers.)

WHITE, GILBERT, known as the author of the Natural History of Selborne, was born at Selborne on the 8th of July, 1720. He was of the family of the Basingstoke, under the Rev. Thomas Warton, father of the poet of that name. On leaving Basingstoke he was admitted a student of Oriel College, Oxford, and took his Bachelor of Arts degree in 1743. He was elected a Fellow of the same college in 1744, and was made a Master of Arts in 1747 and was made a senior proctor of the University in 1752. He exhibited when young an attachment to literature and the study of natural history, and it was to periodical in these studies that he devoted himself from his earliest years. He had a particular interest in the natural history of his native village. Here he lived surrounded by his friends, engaged by his favourite pursuits during the whole of his life: he died on the 26th of June, 1733. Although he had frequently offered of preferment in the church, he declined the offer; and it was not before he had passed through the usual course of the clerical profession; for during the latter part of his life he acted in the capacity of curate at Selborne, and had previously performed the same duties in the adjoining parish of Farnham. The work on which the reputation of White was decided rests on his claim for him a conspicuous position amongst the cultivators of science, as well as the classical writers of Great Britain, in his Natural History of Selborne. This work was first published in quarto, in 1798, four years previous to the death of that author. In it he expressed a chapter on the antiquities of Selborne, a part of the work which has not been often republished with the numerous editions of the Natural History. After the death of Gil-
bert White, Dr. Aikin published a work entitled 'A Naturalist’s Calendar, with Observations in various branches of Natural History,' the whole work being selected from a natural history journal which had been kept by White for twenty-five years. In 1802 the ‘Calendar’ and ‘Natural History’ were published together in two volumes, octavo. In 1813 the ‘Antiquities, ‘Natural History,’ ‘Calendar,’ and some poems of the author’s were published together in one volume, 8vo. In 1826, these works appeared, edited by the Rev. John Mitford, Sir William Jardine, Captain Brown, and other editors. One of the best of the later editions was by the late Edward Turner Bennett, secretary to the Zoological Society, who, under the encouragement of both Dr. White and the Naturalist’s Calendar, and which is enriched with copious notes by the editor, and by Messrs. Bell, Owen, Yarrell, Daniell, Remire, Herbert, and others. The last edition of the Naturalist’s Calendar, 1843, has been published in small 8vo.

The portions of White’s writings devoted to natural history are written in an elegant and pleasing style, and give to the reader something of the enthusiasm of the writer. No one can fail wishing to participate in the quiet pursuits of the author in his rural solitude, after reading his letters, and they have much contributed to spread a taste for natural history in this country. But his letters and essays on subjects of natural history are not mere descriptions, but contain a large amount of original observation which has contributed much to a knowledge of the forms, habits, and instincts of the animals that inhabit Great Britain.

White was peculiarly fortunate in belonging to a family of ancient privilege and wealth. His grandfather was a wealthy family man, and with whom he was in constant correspondence. Four of his brothers are referred to in his letters, and some of them are well known for their literary labours. Most of his brothers and sisters were married, but he died single. He was too much occupied to give much interest to the families of his near relatives, and carefully noted down in his diary the births of his nephews and nieces, who, at the time of his death, amounted to the number of sixty-three. (Preface to Bennett’s edition of White’s Selborne.)

WHITE, REV. JOSEPH, was the son of a poor journeyman weaver of Gloucester, where he was born in 1746. His father brought him up to his own trade, but sent him for a time to school. In 1777, White’s Bampton Sermon was reprinted, and whatever it amounted to, had the effect of inspiring him with a love of reading and study, which he carried so far in his leisure hours, that his attainments at length attracted the notice of a neighbouring gentleman of fortune, who furnished him with the encouragement of a pension. In 1780, White had been taken to London, where he kept; the shell of the animal was carefully preserved in the family, and on being examined by Mr. Bennett, he was found to be the owner of a hitherto undescribed species, and has accordingly named it Testudo Helena.

To Bennett’s edition of White’s Selborne.
thinker; and, though he looked wild and weak, he was actually a man of extreme acuteness. But the slovenly habits which altered his appearance sunk into the texture of his character, and deformed the whole construction. Parr, it may be added, who in one letter characterizes him as uniting to the darkest management the clumsiest execution, always believed that his own and Badeck's were not the only pens he had laid under contribution; his notion was, that another of White's friends, Dr. John Parsons, afterwards the bishop of Coldham, was an auxilium whenever any man or woman, engaged in the preparation of the Bampton Lectures from beginning to end, thought 'without being let into the secret of other persons being also employed.'

We're calculation as to preformation was not disapproved by the new bishop. White was soon after promoted by the crown to a canonry of Christ Church; besides which, having, in 1700, vacated his fellowship by marriage, he was presented by his college to the living of Melton in Suffolk. His subsequent publications were well known. Distant in time from a Latin text, with a Latin translation of Abdallah's Description of Egypt, 1700, 1701; a critical edition of the Greek New Testament, publishing the alterations proposed by Griesbach in the common text, 2 vols. 1700, 1702; and a sequel to this, in 1700, edition of the only one of the synoptic Gospel texts translated by Griesbach, Crisena-Griechischen in Novum Testamentum Synopsis, which appeared in 1701. He died at his residence in Christ Church, 22nd May, 1716.

HEBEY KIRKE, was a native of Nottingham, where he was born 21st March, 1785. He was the son of John White, a butcher of that place, and of his wife Mary, whose maiden name was Neville, and who belonged to a respectable Staffordshire family. He early showed a preference for reading, and had lived long enough to try his hand at composition in prose when he was about seven years old. His first attempts in verse appear to have been of considerable later date; the earliest that is given or mentioned by his biographer is a short poem stated to have been 'written at the age of thirteen.'

His first attempts in verse appear to have been of considerable later date; the earliest that is given or mentioned by his biographer is a short poem stated to have been 'written at the age of thirteen.'

In addition to his Latin and arithmetic, acquired an acquaintance with the French language; but up to this time it continued to be the intention of his father to breed him up to his own business, and one whole day in every week, and his leisure hours on other days were employed in carrying the butcher's board. At last his mother, who appears to have been a woman of some education, as well as of a superior cast of mind, and who had now, in conjunction with her eldest daughter, opened a girls' boarding and day-school, which proved a profitable and satisfactory enterprise to the profits of this plan; and at the age of fourteen Henry, being taken from school, was placed in a stocking-loom, that he might learn the hosiery business. But this proved scarcely more satisfactory or original in its nature; he found it impossible to give his heart, his head, or even his hand with any effect to his employment; and after a year his mother found means to have him placed in the office of Messrs. Cobham and Enfield, attorneys and town-clerks of Nottingham. To make up for the want of a premium, he was engaged to serve two years before the commencement of his apprenticeship, so that he was not articled till the beginning of the year 1802. By this time he had acquired a tolerable knowledge of Latin with very little instruction, and his mother's wish was to improve him. To this purpose he added Italian, Spanish, and Portuguese; chemistry, astronomy, and electricity also engaged his attention; drawing was another of his pursuits; and he played very pleasantly on the pianoforte. He showed likewise a turn for practical mechanics. All this was however occupied by the law, 'to which,' says his biographer, 'his papers show he had applied himself with such industry as to make it wonderful that he could have found time to write as he had done, as his days were anything else.'

By his fifteenth year he had already begun to acquire distinction as a speaker in a literary society in Nottingham, and as a correspondent of various periodical publications, the 'Monthly Preceptor, or Juvenile Library,' the 'Monthly Magazine,' the 'Monthly National,' the 'Monthly Visiter,' and the 'Monthly Mirror.'

The encouragement of the late Mr. Thomas Hill, the proprietor of the last-mentioned work, and of Mr. Capel Lofft, induced him, about the close of the year 1802, to prepare a volume of poems for the press. It does not appear to have been published however till the end of the next year, or the beginning of 1804, when it came out, dedicated, by permision, to the publisher; but her grace after giving her name, forgot to give anything else, or even to notice the poems or their author; and the volume, which was harshly treated by the reviewers, appears to have attracted little of the public attention. It was the best I have ever written; it was mainly written for my dear friend, Mr. Southey, to whom he is principally indebted for the preservation of his memory and the general interest that is still felt about him.

Before his first volume of poetry was published, a great change had been wrought in his opinions, and his whole intellectual being, by his conversion from an indifference to religion and a tendency towards infidelity, to a deep and passionate conviction of the truth of Christianity. What appears to have been most operative in drawing his mind and heart into this new exalted was the circumstance of a young friend, who had been some time before suddenly struck in the same way, being about to proceed to the University, a destination which White had often looked to him. Soon after this, and himself about to enter the University was not; but we are told that, by Mr. Simeon's advice, he read for a year with the Rev. Mr. Granger, of Winteringham in Lindsey, where he studied very hard, and made great progress, during the first term one of the students who had been vacated, for which he was advised to offer himself as a candidate. He passed the whole term in preparing for this object; but his strength and spirits sunk under his exertions, and he was unable to pass the day examination, and was compelled to decline being examined. He had now only a fortnight to prepare for the general college examination: he was, in his exhausted and desponding condition he would have declined that too; but he was prevailed upon to come forward, and was presented the first magister with a very clear hope. He now bent his whole soul to finding the means of following his friend to Cambridge, and getting himself educated for the church. For some time the prospect was very discouraging; but at last the matter was managed, his principal friends wrote to the bishop of Lincoln, which whom he had been recommended, and who procured him a sizarship at St. John's, with additional pecuniary assistance. He quitted his employers, who very kindly gave their consent to this arrangement, in October, 1804. Mr. Southey's memoir is deficient in date, and himself he entered the University is not given; but we are told that, by Mr. Simeon's advice, he read for a year with the Rev. Mr. Granger,

He had now a short visit to London, the excitement of which probably only accelerated the progress of his disease. The next year, at Cambridge, he was again pronounced ill at the college examination. The college now offered him a private scholarship, or post-baccalaurate, and he accepted it; but he visited London, from which he returned to college only to die. His death took place on Sunday, the 13th of October, 1806, when he had just passed the middle of his twenty-second year.

His papers were put into the hands of his friend Southey, who, in 1807, published a selection from his poems and prose compositions, in two volumes, accompanied with the memoir from which the above have been taken. A supplementary volume, consisting of additional pieces, appeared in 1822; and both publications have since been incorporated, and in that form 'The Remains of Henry Kirke White' have been several times reprinted. The edition of 1822 and 1823, therefore that of 1807. This edition, reprinted from the publication of the first collection. The popularity which Henry Kirke White's poetry has enjoyed is owing perhaps more to the touching circumstances of his life, and the attractive picture of his disposition and character than to the merits of the man himself as a diarist, or to its merits.
posed to be the young of the shad. In the fourth volume of the 'Zoological Journal' that eminent naturalist published some valuable papers proving its distinctness as a species from any other member of the Herring genus, *Clupea*, to which it belongs. The whitebait is the *Clupea alba* of Yarrell, and is well figured and fully described in the admirable 'History of British Fishes.' It grows to the length of a man's hand at sides and is of a delicate white colour, whence it derives its name. It appears in the Thames about the end of March or early in April, and during the summer months is abundant, when it forms a dish much valued by the epicure. In the days of Pennant the fisherman's self very irrevocably. I do not appreciate this little delicacy, as he has put on record in his 'British Zoology'; but however in the lower order of epicures, who, he tells us, resorted 'to the taverns contiguous to the places where the whitebait are taken,' are out of the noblest and most learned of the land in the relish of a whitebait dinner. The fishery is continued until September, and the roe would seem to be deposited throughout the summer, as young ones of small size are taken to the end of the season. There are legislative enactments against whitebait fishing, on account of the necessity of using nets with small meshes, but they are now seldom if ever enforced, as it has been shown that no fry of valuable fishes swim along with them.

My grandfather, who immediately returned to Scotland by Dr. Richard Parnell, who gave an account of it in 1838, in its valuable 'Ichthyology of the Frith of Forth' a prize essay of the Wernerian Natural History Society. He remarks, 'I have no doubt that the whitebait will be found to exist in the Frith of Forth as it does in Loch Lomond, with which his father his mother was well acquainted, as it is of quantity, and that the fishermen would find it a new source of income equal or superior to the spooling fishery, did they use the mode of fishing for whitebait that is practised on the Thames.' He also detected the whitebait in great quantities in the Solway Firth, and places the roe of June and July, where however the daintiness of the morsel is unknown to the inhabitants of its shores. The principal food of the whitebait seems to be a very minute species of shrimp, scarcely larger than a moderate-sized flea.

The mouth of the whitebait is so small that the roof of the mouth and tongue of the whitebait are furnished with three or more rows of very minute teeth, a character which at once distinguishes it from the shad, which has those parts destitute of teeth.

**Whitefield, Rev. George,** the founder of one of the two great divisions of Methodism, was, as well as his fellow-labourer Wesley, of clerical lineage, although his immediate progenitors were of the laity. His great-grandfather, the Rev. Samuel Whitefield, of North Lees in Wiltshire, afterwards of Rockhampton in Gloucestershire; in which latter charge he was succeeded by a son of the same name, who died without issue. Another of his sons, Andrew, probably his eldest, lived as a clergyman in his native county, and was the eldest son of this Andrew, was bred a wine-merchant, and followed that business for some time in Bristol, where he married Miss Elizabeth Edwards, a lady respectably connected; but afterwards, having probably been unfortunate, he was transferred himself to Gloucester, and there took an inn. He and his wife, besides a daughter, had six sons, of whom George, the subject of the present notice, was the youngest. I was born in Gloucestershire," says Whitefield himself, in the month of December, 1714. My father and mother, who continued to keep the inn, did her best, in the midst of declining circumstances, to bring him up creditably, had he been a boy. He was not. What he did not expect that she expected more comfort from him than from any other of her children. 'My mother,' says Whitefield, 'was very careful of my education, and always kept me in my tender years (for which I can never sufficiently thank her) from interfering in the least with the tavern business.' He has painted the perversity of his youth in dark colours, but he appears to have been nothing more than a lively and somewhat mischievous and willful boy, with far more promise of good than of evil: with the hard way of stating the matter, he says, 'I was so brutish as to hate instruction; and used, purposely, to shun all opportunities of receiving it (which is what most little boys are in the habit of doing). I soon gave pregnant proofs of an impudent temper. Lying, filthy talking, and at this strong stamp Whitefield would have given when he wrote this to any light or jocular task was much addicted to, even when very young. Sometimes I used to curse, if not swear. Stealing from my mother I thought no theft at all, and used to make no scruple of taking rockets out of the pantry; and the whitebait which she has frequently betrayed my trust, and have more than once spent money I took in the house in buying fruit, tarts, &c., to satisfy my sensual appetite. Numbers of Sabbath have I broken, and generally used to behave in the wantonness of God's servants. Much must I have spent in plays, and in the common amusements of the age. Cards and reading romances were my heart's delight. It has rarely happened that an excited convert has had so poor a case as this to make out against his former life. Moreover, Whitefield is compelled to observe, that he had his occasional religious aspirations from his earliest years. 'Such,' he afterwards says, 'was the free grace of God to me, that, though corruption worked so strongly in my soul, and produced such early and bitter fruits, yet I played composed by the schoolmasters of the Blessed Spirit upon my heart. I had early some convictions of sin. Once, I remember, when some persons (as they frequently did) made it their business to tease me, I retired to my room, and after much crying down, with many tears, prayed over the 118th Psalm. I had always in fact a good and sensitive heart, and never was capable of any hardened or deliberate wickedness. Even when he picked up the halfpence or other small change there was a look in his eye, and he seemed to consider part of the money, he tells us, to the poor. By the time he was ten years of age, too, he had formed the wish of entering the church. 'I was always,' he says, 'fond of being a clergyman, and used frequently to imitate the minister's reading parts. An early doubt was inspired by the pleasure he had already begun to take in the exercise of his fine voice and power of declamation, which were among the greatest of his personal gifts."

'He was placed at the grammar-school of St. Mary de Crypt in his native city, when he was about twelve, and here he made considerable progress in Latin, distinguishing himself besides in delivering the speeches at the annual visits of the corporation, and also in acting (often in girls' clothes) playlets at Christmas. From the gratification of the magistrates. But after a time he got tired of this. 'Before I was fifteen,' he proceeds, 'having, as I thought, made sufficient progress in the classics, and being sent away to London, he set aside from the confinement of a school, I one day told my tutor I believed her circumstances would not permit her to give me a university education, more learning, I thought, would spoil me for a tradesman, and therefore I judged it best not to go to Oxford or Cambridge; and that but my corruptions (?) soon got the better of her good nature. Hereupon, for some time I went to learn to write only. But my mother's circumstances being much on the decline, and being tractable that way, I began to assist her occasionally in the public house, till at length I put on my blue apron and my snuff-box, washed mops, cleaned rooms, and in one word became professed and common drawer for nigh a year and a half.'

This point of abatement to which he had got seems to be sufficient to save him from his own modesty, that worldly humiliation and dishonour proper to form part of a history such as his. After about a year, his eldest brother having married, his mother left the inn; and Whitefield, finding that he could not agree with his sister-in-law, followed his mother in a few months. 'My mother then,' he says, 'though she had but a little income, to have a bed on the ground, and live at her house, till Providence should point out a place for me.' But it appears there neither mother nor son was satisfied. As it had given up the idea of the latter yet making his way to the university, having been a long time lived with my mother for some considerable time,' Whitefield goes on to state, 'a young student, who was once my schoolfellow, and then a scrivener of Pembroke College, Oxford, came to pervade the matter, and told me he wished to have the use of some terms that his academy had not been able to pay. Amongst other conversation, he told her how he had discharged all college expenses that quarter, and saved a penny. Upon that my mother immediately cried out, 'That will do for
my son." Then, turning to me, she said, "Will you go to Oxford, George?" I replied, "With all my heart." Whereupon, having the same friends that this young student had, my mother without delay waited on them. They promised their interest to get me a servant's place in the same college. The result was, that he went back to school, where, he states, he now spared no pains to get forward in his book; and that he was admitted a servant of the college in 1735. As he had left school the religious element in his character had been strongly developed. His own account is that for a twelvemonth he had gone on in a round of duties, "receiving the sacrament monthly, fasting frequently, attending constantly on public worship, and paying other attentions to the Word of God in private." He was thus in the fittest temper of mind for joining the Wesleys and their associates, who had been already for some years known in the University by the name of Methodists. It is not our province to proceed his career here. He was introduced to them about he had been about a year at college, and soon showed that he was to be outrun in zeal by no one. It had happened that, before he and the Wesleys met, Whitefield had for nourishing his devoted temper, by the sermons and books to which they had devoted themselves—those of Thomas à Kempis, Scougal, and Law.

Whitefield was ordained deacon by Bishop Benson, of Gloucester, 26th June, 1736. Soon after, he returned to Oxford, and, in his degree of deacon, preached a most extraordinary sermon. Even the doctrine he delivered was not so novel and arousing as the manner in which he delivered it. Such earnestness, such passionate enthusiasm had never before been heard in the Church of England. He seemed almost to have taken the church in the place of the nation. But even this vehemence lay quite as much in the voice and action as in the language of the preacher. Whitefield's voice, which is affirmed to have been so powerful as to be audible at the distance of a half mile, was that kind of attention that he had most general testimony to have been in all other respects one of the most effective for the purposes of eloquence ever possessed by man: capable of taking every possible tone of emotion, and, whether poured forth in thunder or in soft music, reaching for and striking to the heart with irresistible power and effect. Then he gesticulated, he stamped, he wept with a tempestuous abandonment to which the most successful efforts of the counterfeit passion of the stage seemed tame and poor. He first came up to London in 1737, to officiate for a time in the chapel of the Tower; but his first sermon in the metropolis was preached in Bishopsgate church. He then officiated for a few months as curate at Dummer, in Hampshire. While he was here he received from his friends the Wesleys, who were then in Georgia, in North America. This visit inspired him with a determination to go to the Western world. With this he immediately resolved to comply, but before leaving England he went to pay a farewell visit to his friends in Gloucester; and in that city and Bristol, and afterwards in London, he preached to such over-flowing audiences, and with such extraordinary power, as made the whole country ring with his name. Breaking away however from all the inducements that were held out to keep him at home, he embarked for Georgia on the 23rd of December, 1737. Although it was not till the end of January following that, owing to contrary winds, the vessel got fairly under weigh, about the very time that the ship which brought Wesley back to England was getting into the port from which Whitefield had sailed.

He arrived in America in the month of April, and towards the close of the year. He then returned to England, mainly with the view of raising subscriptions for an orphan-house which he had established in Georgia, and which continued to be a principal object of attention with him during his life. Nevertheless, he continued to preach in associations and the Wesleyan churches, which may be said to have blown into a flame the sparks kindled by their previous separate exertions, and to have established Methodism as a popular faith. It was Whitefield who set the first example of preaching in the open air, which he did on the afternoon of Saturday, the 17th of February, 1739, on Hambledon Mount, at Rose Green, to the collins of Kingswood, near Bristol.

But this time forward his life was spent in incessant movement from place to place, and exercise of his wonderful power of exciting and swaying the feelings of all orders of persons by his peculiar pulpit oratory. He repeatedly revisited America, and traversed the whole extent of the British possessions there; when, on this side of the Atlantic he generally made a yearly round through England and Ireland; he was several times in Ireland, and in 1754, on one of his voyages to America, he spent a short time at Lisbon. To the end of his life his popularity as a preacher remained almost unimpaired; multitudes, at least, continued to crowd to him wherever he appeared, and white and black, young and old, came to hear what he had to tell. As in the case of Wesley also, the more extravagant effects which his appeals had at first in many instances produced soon ceased to be commonly exhibited. Nor was it only the unlettered that he interested and delighted. It was in an year of great distress, when he was preaching in Huntingdon, who made him one of her chaplains. This connection introduced him to the highest circles both of rank and literature in the metropolis; and among his admirers are frequently to be found numbers of court beauties and persons of both sexes of the first distinction in the world of fashion, but such men as Chesterfield, Bolingbroke, and Hume. So also in America he was listened to with wonder and compliance by Benjamin Franklin.

Whitefield and Wesley were in various respects very unlike one another, and, as is well known, they did not long continue to co-operate. They quarrelled, so early as in 1741, about the great question of predestination; Wesley, in the meantime, was publishing From the Sabbath to the Litany, an attempt to reconcile the two systems. Whitefield, contrary to what might have been expected, standing up for the Calvinistic system of irresistible free and eternal decrees of election and reprobation. They never came to agree upon this high matter; but they, comparatively opening the eyes of a million, that by the gospel might be saved, soon cooled down, and, although they never again acted in concert or association, their occasional intercourse was renewed long before they left the world. Whitefield, on the contrary, always looked upon Wesley as the man who ought to preach his funeral sermon; and Wesley actually performed that office for his old friend.

Whitefield lost his mother, in the seventy-first year of her age, in the spring of 1740, and about the same time, with great regret, he found that he and his kin were in a state of war. In the spring of 1740, he applied to two of his friends, a Mr. and Mrs. D. to ask if they would give him their daughter to wife, at the same time telling them that they need not be afraid of sending him a refusal; "for I bless God," said he in his singular epistle, "if I know anything of my own heart, I am free from that foolish passion which the world calls love. But I have sometimes thought Mrs E—- would be my helpmate; for she has often been impressed on my heart." This attempt came to nothing; he therefore went on, at the expense of his health as he alleged, to England to Mrs. James of Abercawberry, a widow of between thirty and forty, who, he intimates, was neither rich nor beautiful, but had become religious after having spent her life like the rest of the world. When he wrote, his child would be a boy, and become a preacher of the gospel; he was right as to the sex, but the infant died at the end of four months. His wife died in 1768; and one of his friends, Cornelius Winter, has recorded that Whitefield and she did not get happily together, that she certainly did not behave as she ought, and that her death set his mind much at rest.

Whitefield himself, whose health had began to give way about 1757, died at Newbury Port, near Boston, in the Parish of Reading, 29th August, 1770. His printed works, besides an edition of Clarke's "Commentary on the Bible," which he published in 1728, consist principally of sermons, either printed from his own manuscripts or taken down by reporters as delivered in a public place. He published a copious journal of his life and labours, and of the various volumes of letters, amounting to 1405 in all, and extending over the time from July 1765, to within a week of his death. A collection of his sermons, tracts, and letters in 6 vols. was published by London, 1717; his journals, like Wesley, he published in his own lifetime; the second edition, with considerable corrections, appeared in 1758. A Life of Whitefield, by the Rev. J. Gill, was published by the College Church of Glasgow, appeared in 2 vols. at London, in 1819; and a volume of nearly 800 closely printed pages, entitled 'The Life and Times of the Rev. George Whitefield,' by Robert Philip, was published.
in 1838. The latter work is one of considerable talent, but its convenience is greatly impaired by the almost entire absence of dates. Much information about Whitefield is to be found in Southey's Life of Wesley; Jay's Memoirs of the Life of Charles Sumner; 2 vols., London, 1809; and The Life and Times of the Countess of Huntingdon, 2 vols., London, 1840.

WHITEHALL, a part of the city of Westminster which extends from near Charing Cross to Downing Street, and from the Chambers before, in his case, the close of 1838 are situated several of the chief public offices of the British government, as the Admiralty, the Horse Guards, the Treasury, the Board of Trade, and others. Whitehall was formerly the site of an extensive palace, which was occupied temporarily by Henry VIII., Queen Elizabeth, James I., Charles I., Cromwell, Charles II., James II., and William III.

The palace was originally built by Hubert de Burgh, justiciary of England in the reign of Henry III. He began to the area of Blackfriars, and by Nov 9, 1246, was sold, to Walter de Grey, archbishop of York. From that time it was called York Place, and became the palace of the archbishops of York, who occupied it for three centuries. The lastest intaglions made which it was Cardinal Wolsey. He made very extensive additions to the buildings, and lived in a style of sumptuous magnificence scarcely surpassed by King Henry. The King often visited the cardinal, and was entertained with princely hospitality. On the death of the cardinal, the king's favour, and he was then ordered to leave York Place, and Henry took possession of it himself. It was not allowed to be called York Place any longer, and it soon afterwards received the name of Whitehall, probably from the brightest and most ornamental of its parts, the Harcourt, with the old buildings. Among the additions made by Henry were 'divers fair tennis-courts, bowling-alleys, and a cock-pit.'

After James I. came to the throne, the greatest part of the palace was in such a state of decay that in 1608, he began to pull down and rebuild. A stately banqueting-house had just been completed, when, in 1619, it took fire, and was entirely burnt. James now resolved to rebuild the whole. Inigo Jones was appointed surveyor-general of the buildings, and the work was directed by Sir Charles Cavendish, Wolsey's former chief, and it was allowed to build York Place, and Henry took possession of it himself. It was not allowed to be called York Place any longer, and it soon afterwards received the name of Whitehall, probably from the brightest and most ornamental of its parts, the Harcourt, with the old buildings. Among the additions made by Henry were 'divers fair tennis-courts, bowling-alleys, and a cock-pit.'

WHITEHALL, [Cumberland.] WHITEHEAD, PAUL, was the youngest son of Edmund Whitehead, a tailor, of Castle Yard, Holborn, London, where he was born 6th February, 1710, o.s., being Paul's day, from which circumstance he is said to have derived his Christian name, ludicrously unsuitable to his character, and made more memorably ridiculous by his brother satirist Churchill's well-known

...be a whitehead and baptize a Paul!...

On leaving school he was placed as apprentice to a mercer in the city; but he afterwards found means, in what way is not exactly known, to procure himself a seat at one of the inns of court as a student of the law. It does not appear that he was ever called to the bar; but in 1735 he obtained whereabouts to live in idleness, or without a profession, by marrying Anna, the daughter of Mr. Wright, Dyer, Bar of Spain's Hall, Essex, with whom he received a fortune of ten thousand pounds. The lady, who did not live long, is stated to have been young, but very homely in person and little better than an idiot. Two years before this he had published, as the first poem, entitled 'The Table upon the ministry, which he inscribed to Pope, and which brought him both into notice with the public and into favour with the opposition, then headed by the Prince of Wales. This was followed, in 1739, by another piece, entitled 'Mannors,' in the same strain, but written with so much more daring, that, on the motion of Lord Delawar, the author and his father, Dodsley, were forewarned that the House of Lords, and Whitehead found it necessary to abrade for a time. He was now, along with Ralph (upon whom he had poured unparisoning abuse and contempt a few years since), a Dr. Thomson, and others, one of the pack of literary lackeys kept about him by Bubb Dodington; and he distinguished himself by his zealous exertions in the cause of his patron, not only by his pen, but at elections and in other ways. Besides 'The justiciary took the name, 'Honour,' which he published about the same time, and 'An Epistle to Dr. Thomson,' in 1755, were the principal productions of this part of his life. Another of his patrons and bosom associates was his gentleman cousin, Lord Desperance, Whitehead made one, with Dashwood, Sir Thomas Stapleton, Wilkes, and others, in the infamous revellies of Midsummer Abbey, and engaged them to give him some further help; and Whitehead struggled on till he was elected a Fellow of his college in 1742. He seems to have now intended to take holy orders, as had been done by his elder brother John, who held the living of Fersenhof, in the diocese of Wroclaw, in Saxony; for the purpose of entertainment, was changed by his being selected, in 1745, to be tutor to the son of William, third Earl of Jersey (the same who afterwards succeeded to the title, and was the father of the present earl). About a year after this, Whitehead resigned his fellowship. In 1754 he went abroad with his pupil and Viscount Nuneham, the son of Earl Harcourt. After spending a summer at Ribeins and a winter at Leipzig, they proceeded to Vienna, and thence to Italy, returning through Switzerland, Germany, and Holland, and reaching home in September, 1756. During his absence from England, Whitehead had, by the interest of his noble patrons, been appointed to the post of secretary and registrar to the order of the Bath; and the year after his return to the metropolis, he was created a poet laureate, vacant by the death of Colley Cibber. Both these offices he held till his own death, on the 14th of April, 1798.

Whitehead began very early to be known as a writer of verses; and his poems, consisting of epistles, tales, essays, odes, &c., were twice collected and printed under his own direction, first in 1754 and again in 1774: a third edition was published by Mr. and Mrs. Johnson's 'Memoir of Dr. Thomson,' in 1798; and they are also inserted in Chalmers's edition of the 'English Poets,' 21 vols. 8vo, 1810. They are now however utterly neglected and forgotten. His most esteemed production is his tragedy of 'The Emperor of China,' which was first brought out at Drury Lane in 1750, and long continued a success.
'Creusa, Queen of Athens,' first produced in 1754; of 'The School for Lovers,' a comedy, in 1762; and of 'A Trip to Scotland,' a farce, brought out with considerable success in 1772.

WHITETHROAT, Motacilla sylvia, Linn.; Sylvia cineria, Auct.; Currucina cinerea, Bech.ah.

Description.—Male.—Top of the head and space between the eye and the bill ash-colour; other parts grey, strongly tinged with rust-colour, which last predominates prenently in the tips of the back. Wings blackish, tail-feather covers bordered with very bright rusty; quills edged with white; throat and middle of the belly pure white; breast slightly tinged with rose-colour; sides and abdomen rusty grey; the lower tail-feathers; quills of the wing: length, except the most external, which is much the shortest; this last has the outside bar and the extremity pure white; the succeeding feather is only terminated with whitish. Length 5 inches.

Female.—With the tints less pure and the upper parts more clouded with rusty; white of the throat and of the external tail-feather clouded with rusty; no rosy tinge on the breast.

Young.—With more rust-colour on the upper parts; space between the eye and the bill white, and the rusty borders of the wing-coverts wider; external quill edged with rusty, instead of white.

This is the Pauvite grise or Grasette of the French; Maccroppetta delle of the Italians; Klapper Grosnücke, Puhle, Grauliche, Rostgraue, and Grauhnügge Heckernasymucke of the Germans; Kognetter and Mesar of the Swedes; Common Whitethroat, Magey, Maggy-cut-throat, Whey-beard, Wheiti-sky-bird, Uff, Charlie Mark, Pegguy, Pegguy-white-throat, Charr, and Wauhite of the modern British; and Y gnedisfyyn of the antient British.

Geographical Distribution.—Denmark, Sweden, Russia, Siberia, Germany, Holland, France, Provence, Spain, Sicily, Salyria, and Turkey.

A regular summer visitor to the British Islands, arriving about the third week in April, and departing in autumn.

Habits, Food, &c.—The principal food of the Whitethroat consists of insects: it is very fond of caterpillars, and is an considerable consumer of berries and smaller garden- fruits, such as raspberries, currants, &c., among which they and their young make much havoc in July and August. A dwarf bush or a low tangled thicket of brambles, nettles, weeds, and rank grass, is generally selected for the nest, which is seldom found at a greater distance than two or three feet, and lies the outside framed almost entirely of the stems of dried grass; the upper part of the nest is very thin and flimsy at the sides, and the inside is lined with finer grass stuff, or panicles. The eggs, which amount to four or five, are white with a greenish tinge, spackled and spotted with ash-brown and ash-green of two shades.

'Some of the notes of the voice of this bird,' says Mr. Yarrell, 'are nightingalish, other the beginning of January, but will not suffer itself to be outdone. When the nightingale raises its voice, it also does the same, and this its utmost to get above it; sometimes in the midst of its song it will run up to the nightingale, and stretch out its neck as if in defiance, and whistle as loud as it can, striking in the face; if the nightingale attempts to peck it, away it is in an instant, flying round the avairy and singing all the time.'

There is another Whitethroat, also a summer visitor to these islands, and first noticed here by the Rev. John Lightfoot, who found it near Bulstrode in Buckinghamshire, the same who discovered the Reed Warbler in this country.

This is the Sylvia Currucia of Latham and authors; Currucina garrula, Brehm; and is the Pauvite Bardin of the French, Pauvite Dron, and Klaensch弼teny Kerpersmucke of the Germans, Bigiarella of the Italian, Lesser Whitethroat of the English.

Habits, Food &c.—The food of this Whitethroat is the same as that of its more common congener. 'It frequents,' says Mr. Yarrell, 'high and thick hedges, shrubberies, orchards, and gardens, and is occasionally to be seen in two instances with a beautiful tinge of carmine on the breast.

Geographical Distribution.—Denmark, Sweden, Russia, temperate and warmer parts of Europe, Asia, and the Dees. In these islands it is rare as far north as Northumberland, and rarer in Ireland, where it does not appear to have been seen. It arrives and departs about the same time as the Common Whitethroat.

Common Whitethroat.
ash-grey and light brown. The eggs in number are four or five; and Mr. Jenyns has remarked that incubation commences about May. (British Birds.)

In Germany it is termed Das Müllerchen, or the Little Miller, from some of its clacking tones being supposed to resemble the noise of a mill, according to Bechstein, who remarks that as these notes are heard more distinctly than the others, they are erroneously thought to be its whole song; but the rest, he adds, though certainly very weak, is so soft, so varied, and so melodious that it surpasses other warblers. Whilst singing in this under-tone, says Bechstein in his account of this bird, it is constantly hopping up and down the rushes, but when going to and from the nest it claps, claps, and stops and employs the whole strength of the larynx to pronounce this syllable. To enjoy the beauty of its song, Bechstein remarks that it should be alone in a room, and then no other singing-bird is more agreeable, as it rarely utters its call. Both Sweet and Blyth speak favourably of its song, though the former, who gives a very pleasing account of one which he bred up from the nest, says it is not so agreeable as that of most of the other species of warblers.

WHITGIFT, JOHN, a religious house situated between Broad Street and Threadneedle Street, London. While at this school he lodged with his aunt in St. Paul's Churchyard, a staunch Catholic, to whom he gave offence by his aversion to the ceremonies of the church. She in vain endeavoured to reconcile him to the establishment, and he grew more and more at variance, and at last determined to keep him no longer under her roof. On sending him home to his father in the country, she said that she thought at first that she had received a saint into her house, but now she could not have called him a saint, for he went to the University of Cambridge, where he was entered at Queen's College. Thence he soon removed to Pembroke Hall, where he was a more Protestant character. Bishop Riches being the master, and Bradford the martyr, and General Henry, head of that college. In 1554 he commenced Bachelor of Arts, and in the following year was elected fellow of Pembroke. At this college he formed a strong attachment to the master, Dr. Andrews, through the influence of his father, a Catholic, and pursued his studies at Cambridge in the year of King VI., when the Protestant faith had long been protected, he made no secret of his opinions, nor did he desist from making known to many other members of that University. In 1556, on the account of Cardinal Pole, then archbishop of Canterbury, and the papal legate, ordered a visitation of the University. And three commissioners to Cambridge were sent, who, says Whittig, was so much alarmed at the vocation that was coming that he determined to escape by going abroad. He was therefore examined in the presence of Mr. Pembroke, and he was so determined to escape that the commissioners were much surprised that he did not make a further show of it, for not only the public opinion and characters of men were examined, but there was a very strict private examination. His examination was so full, and thorough, that the whole examination was not finished till the next day. For this he was highly distinguished by Dr. Pembroke, and was made a fellow of Pembroke College. He was removed to Trinity in 1557, and was elected a fellow of that college in 1558, and afterwards became president of Pembroke College, and then president of Trinity. He was appointed master of Pembroke College, and was a man of great wealth, and much distinguished in his person. He continued his residence there for upwards of fifteen years, being distinguished for his learning and talents, and holding many high offices and preferments. His lectures as the Lady Margaret's professor of divinity obtained him much distinction. In 1584 he was chosen master of Pembroke Hall, but only remained in that situation for three months; for his fame as a preacher having obtained him the honour of preaching before the queen, he acquitted himself so well that she made him her chaplain, and shortly after became master of Trinity College, Cambridge. In the same year also he took his degree of D.D., and succeeded Dr. Hutton as Regius professor of divinity. In 1586 the bishop of Ely, Dr. Cox, whose chaperlain he had been for some time, conferred upon him a prebend of Pembroke Hall.

Meanwhile Dr. Whitgift was taking an active part in the government of the University, for which purpose he drew up, with the vice-chancellor and some of the heads of colleges, a body of new statutes. He was very strict in enforcing discipline, and he established a new established church; and his activity in restraining any laxity of doctrine or practice in the University, while it brought him into much contention and raised him many enemies, may be regarded as the main cause of his further advancement in the church. Mr. Cartwright, the Lady Margaret's professor of divinity, having in his lectures attacked episcopacy, the Church Liturgy, and other institutions settled at the Reformation, Dr. Whitgift challenged him to a disputation, which took place before the court of the King's Bench, and the judicial proceedings against Cartwright were pending, which ended in his expulsion, he wrote an elaborate composition of these schismatic opinions, and had it before archbishop Parker. In 1571 he filled the office of vice-chancellor of the University, and in the following year was elected provost of the Lower House of Convocation. At this time a book was published, called 'An Admonition to the Parliament,' being a violent attack upon the whole constitution of the Reformed church, its sacraments, its Liturgy, its discipline, and its bishops, which Cartwright held the church as a most dangerous book, and Dr. Parker, then archbishop of Canterbury, who had already had many opportunities of judging of Whitgift's zeal and capacity, and their want of concord in the national church. He wrote the declaration of the archbishop, and was appointed to deliver the declaration and to examine the archbishop's advice and assistance of the archbishop. His answer was written in the same year as the Admonition, and was an able work of great learning, and deserving much skill in composition. He treated the doctrines of his opponents with severity, but in a manner temperate, dignified, and moderate, and had been supported by great preachers, to such as Dr. Whitgift had been supported by other preachers, to such as Do. Whiggift had had been supported by great preachers, to such as Do. Whiggift had had been supported by great preachers, to such as Do. Whiggift had had been supported by great preachers, to such as Do. Whiggift had had been supported by great preachers, to such as
exercised himself to repress papacy on the one hand, and dissent or Puritanism on the other, and repeatedly obtained the thanks of the Privy Council for his success. At the same time he protected the rights and interests of the clergy of his diocese. The strictness of his orthodoxy and the severity of his discipline were displayed at a time most favourable for his further promotion. Grindal, then archbishop of Canterbury, had given great offence to the queen by his leniency to schismatics, and at length, on refusing to yield to the select orders in suppressing (on the meetings of the clergy for worship and the discussion of religious subjects in private houses), he was suspended from his office by the Star Chamber, and confined to his own house. Grindal, a meek and timid man, was anxious to reside in his own house and enjoy his own books; and for this purpose he offered the archbishopric to Whitgift, which he however declined to accept during the life of Grindal. That prelate soon afterwards died, and in 1583 Whitgift succeeded him.

The queen's zeal for orthodoxy was now at its height, and her new archbishop lost no time in proving his determination to enforce conformity. He immediately required all the clergy to subscribe to three articles before they were permitted to execute any ecclesiastical function, viz.:—1. That the head of the church was the supreme pontiff, 2. that the Ordinal and Book of Common Prayer contained nothing contrary to the Word of God; and 3. that the Thirty-nine Articles were to be admitted as agreeable to the Holy Scriptures. He suspended all the clergy who refused to subscribe to these articles, introduced greater strictness in admission to holy orders, and exacted compliance with all the forms and ceremonies of the church. He also obtained from the queen a new ecclesiastical commission, with greater powers than any of the preceding commissions—whom he never failed to consult in every matter of importance. From his high station in the church and his personal influence with the queen and her councillors, his biography may be said to be the ecclesiastical history of England during the remainder of the reign of Queen Elizabeth. Religion was the order of the day, and no one's conscience, however cruelly it does not appear to have been part of Whitgift's character, he was a stern disciplinarian—flexible in his principles, and resolute in their application. Doubt was unknown to him, and he would not allow it in others. Thus he addressed himself to the bishop's see, and directed the ministers, 'And here I do protest, and testify unto your lordships, that the three articles, whereunto they are moved to subscribe, are such as I am ready by learning to defend, in manner and form as they are set down, against all misliking England or alike.' With this pretended spirit of conviction of right, he regarded all dissentients as obstinate schismatics unwilling to be convinced of their errors, and therefore deserving of punishment. His chief object, however, was to make non-conformists from the church, and to seek out and punish heretics. To this duty he repeatedly affirmed that 'her majesty moved and earnestly exhorted him, with strait charge, as he would answer the contrary;' and he would listen to no solicitation to bend him from his serpentine hearing on threats against his person, he writes to Lord Burghley, 'And if there be no other remedy, I am content to be sacrificed in so good a cause: which I will never betray, nor give over; God, her majesty, the laws, my own conscience, and duty, being with me.' The Lord Treasurer Burghley, who had always been his firm friend, often expressed his disapprobation of Whitgift's severity, and contended wisely, as well as humanely, that the ministers of the church ought not to be questioned upon minute points of doctrine, unless the person concerned is suspected of being in the subservience of the unauthorised, and 'wished that the spirit of gentleness might win, rather than severity;' yet in spite of the remonstrances of that great man, and even of the council, Whitgift persisted in maintaining an inquisition in the church which drove many into dissent.

Whether convinced of the evils of such inquisition, or at length overcome by the persuasion of others, we find him, in 1586, assenting to the advice of Secretary Walsingham, and requiring that all ministers, who were hereafter to enter into living or the ministry, leaving unmolessted the clergy already in the enjoyment of benefices, provided they read the Book of Common Prayer according to the appointed ritual.

In order to obtain a uniform opinion, he obtained from the court of Star Chamber, of which he was a member, a decree to restrain the liberty of the press. By this decree, of June 23, 1585, no printing-presses were allowed anywhere but in London, Oxford, and Cambridge: the number of these was to be settled by the archbishop and the bishops of London; no book or pamphlet was to be printed without having been perused by them, and all books selling, uttering, or even binding unauthorised books were liable to three months' imprisonment.

Notwithstanding the strictness of his views in matters of ecclesiastical conformity, he was prepared, if necessary, to endure hardship or severity. His old friend the Earl of Salisbury indeed attested, 'that there was nothing more to be feared in his government, especially towards his late time, than his mildness and lenency. Pregnant instances of how leniently he administered the dread of the papacy, in the pardoning of Udall, and others condemned to die for their sedition: and for the dismission of Cartwright and even other contentious ministers from the Star Chamber. And divers other gentlemen had the like favour obtained for them, and pardoned from both fine and imprisonment, for entertaining the presses and printers of most malicious vituperative books, secretly printed and dispersed.' His respect for learning and learned men was evident on various occasions. He led Whitgift's address 'to the learned antiquary Stow dedicated to his 'Anals' in 1600, and said 'that his grace's great love and affection to all good studies in general, and to antiquities in particular, had been so singular, that all who liked and loved good learning strongly esteemed him their principal and greatest patron.'

The archbishop always took a lively interest in the management of public charities, and contributed substantially to their foundation and support. In 1581 he entered into a contract to build a hospital for the poorest of the poor, in the city of Canterbury, enlarged its endowments, and placed it upon an improved foundation. He also built and endowed, entirely from his own revenues, a hospital, free-school, and chapel at Croydon in Surrey, and contributed considerably to the foundation and support of a college in London. He also stated in the House of Commons, about the same time, that the net income of the archbishopric did not exceed £2200.

On the death of Queen Elizabeth Whlgift was said to have asked King James II to have his translation of the government and Liturgy of the church, and in order to conciliate him he deputed Dr. Nvyl, dean of Canterbury, to wait upon his majesty in Scotland, and to recommend the Church of England to his favour and protection. But the tenor of Whitgift's correspondence from this time shows him to have been in continual apprehension of change. He had been so long accustomed to rely with certainty upon the firm friendship of the queen, that he was not encouraged to trust the intentions of the archbishop. He could not but fear that the latter, who had stated in the House of Commons, about the same time, that the net income of the archbishopric did not exceed £2200, would have been more than content to have the situation of the spiritual lordships of the church in England, and to have enjoyed the undisturbed possession of the diocesan revenues, without any further interference from the crown, so far as affected the Church of England. He had therefore cause to fear that the appointment of Lord Whlgift, as archbishop of Canterbury, would be accompanied with the removal of that from his diocese.
Whigirl however did not live to assist in the consultations of this commission. Soon after the conference, he caught cold while suffering from the effects of his lying so long on the floor. On Sunday, after a long interview with the king, he was seized with a fit, which ended in an attack of palsy and loss of speech. The king visited him at Lambeth, and said that if it should be his lot to die, he would pray for his life; and that if he could obtain it, he would put himself in the hands of Divine Providence. The last prayer was for the church of God, and one of his last exclamations declared his joy that he should die at a time wherein he had rather give up to God an account of his heart and actions, than to be delivered from the execrations among men.

Amidst the latter reflections in his barge, and on the following Sunday, after a long interview with the king, he was seized with a fit, which ended in an attack of palsy and loss of speech. The king visited him at Lambeth, and said that if it should be his lot to die, he would pray for his life; and that if he could obtain it, he would put himself in the hands of Divine Providence. The last prayer was for the church of God, and one of his last exclamations declared his joy that he should die at a time wherein he had rather give up to God an account of his heart and actions, than to be delivered from the execrations among men.

and, after having taken priest's orders, he set up a grammar-
school of his own about 1501, probably in London. All
that is known of the rest of his life is that he was placed in
1530. But, besides his schoolbooks, Whittington wrote
also Latin verse with very superior elegance; and he is re-
membered in modern times principally as the last person who
was made poet laureate (poeta laureatus) at Oxford. This
honour he obtained in 1519, on his petition to the congrega-
tion of regents of the University, setting forth that he had
then spent fourteen years in studying and twelve in teach-
ing the art of grammar (which was understood to include
rhetoric and poetry or verse-writing), and praying the
regents to reward, or graduated, in the said art. These
academical graduations in grammar, on occasion of which,
as Warcon states, 'a wreath of laurel was presented to the
new graduate, who was afterwards usually styled poeta
laureatus,' are supposed to have given rise to the appella-
tion as applied to the king's poet, originally styled the king's
verifier (versificator), who seems to have been merely a
graduated grammarian or rhetorician employed in the ser-
vice of the king. Whittington, as had been customary, on
obtaining this laureate, or at least his highest, Latin verse,
which were published by being stuck up on the great gates
of St. Mary's church. After this he used to style himself
on his title-pages not only master of grammar (grammatices
magister), but chief poet of England (protovates Anglice).
The title of Poet Laureate, or Poeta laureatus, was adopted in
1737. It is known that Whittington was afterwards admitted to the
degree of Master of Arts. Whittington's Latin verse has
been highly praised. Of his 'Epigrammata' (printed in 1537),
and of the four epigrams which he composed in dedication
to Charles Brandon, duke of Suffolk, Sir Thomas
More, and the poet Skelton (who, like himself, had been
made poeta laureatus at Oxford, in 1489), Warcon says,
'Some of the lines are in a very classical style, and much in
the manner of the earlier Latin Italian poets. (Hist. of
Eng. Poets, ii. 441, &c.)

WHITLEYSEY. [CAMBRIDGESHIRE.]

WHITWORTH, the name of an antient Staffordshire
family, which has produced two diplomats of some
名望.

CHARLES WHITWORTH, eldest son of Richard Whitworth,
of Blowerpipe, in Staffordshire, was born at Albaston,
about the time of the Revolution, and died in 1725,
at London. He was an attaché of Mr. Stepney at several courts,
and in 1718 was himself appointed resident to the Diet at
Ratisbonne. In 1704 he was named envoy to the Court of
Russia; and in 1710 he was again sent to that court
with the title of ambassador extraordinary, to propitiate Peter
the Great, irritated by the arrest of his ambassador in the
previous mission. But the situation at the court of
Whittington was subsequently—Plenipotentiary to the Diet
of Augsburg and Ratisbonne in 1714; envoy extraordi-
inary and plenipotentiary to the king of Prussia in 1716;
and envoy-extraordinary to the Hague in 1717; again
plenipotentiary at Berlin in 1719; and representative of Great
Britain in the character of ambassador extraordinary and
plenipotentiary at the congress of Cambrai in 1722. He
was created Baron Whitworth of Galway, in 1721, by
George I. Lord Whitworth retired into private life in 1724,
died in the ensuing year, without issue. His 'Account
of Russia as it was in the year 1710' came into the bands of
Horace Walpole, and was printed by him at the Shrews-
bury press. In the preface Walpole mentions that many
viewals of it and the Baron's life letters and papers were
in the possession of his relations.

CHARLES WHITWORTH, grandson of Francis, a younger
brother of the preceding, who was M.P. for Minehead
in Somersetshire, surveyor-general of the Woods and Forests,
in 1718, was himself sent to teach at University
of Edinburgh, and in 1714, at London. He was then
sent to be educated at Tunbridge
school, and, on his leaving that place, procured him a
commission in the army. How long he served in the military
diplomatic service does not appear, but in 1786 he
found himself to be sent to the court of Poland as minister
plenipotentiary.

In 1786 Whitworth was sent as envoy extraordinary
and plenipotentiary to Russia. In 1800. Whitworth acquired and retained to the last a marked
ascendency over the councils of the Czarina Catherine II.
After her death (February, 1796) his troubles began. Paul I.,
resolved to undo everything that his mother had done, re-

WIC

Wichmann published several works on various departments of medicine, the most remarkable of which is his 'Ideen zur Diagnostik,' published at Hanover in 1794, in three volumes, octavo. This work has gone through several editions, and is possessed of great practical merit. In all his works he points out with a force the origin of diseases in external circumstances, and proposes correct hygienic rules for their prevention. His great fault as a writer has been considered to be his want of general views and the manner of his details. He wrote several other works on various diseases and their treatment, which were all published at Hanover. He died on the 12th of June, 1804. (Biographie Médicale.)

WICK. [CATHEDRAL] Wick, county of [WICKLOW, COUNTY OF.] WICKLOW, COUNTY OF., one of the twelve counties into which the province of Leinster in Ireland is divided. It is bounded on the north by the county of Dublin, on the north-west and west by the county of Kildare, and on the southwest by the county of Carlow. It is the part of the county of Wicklow near the town of Carnew, is 38 miles; the greatest breadth at right angles to the length, from the border of the county of Kildare to Wicklow Head, southeast of the town of Wicklow, is nearly 30 miles. The area, as stated by the Survey, is 177 square miles, 1 road 7 poles, or nearly 782 square miles; of which 499,988 acres 2 roads 27 poles, or about 780 square miles, is land; and 1088 acres 2 roads 20 poles, or about 18 square miles, is water. The population, in 1821, 121,557, giving rather more than 6,750 inhabitants to a square mile; in 1831, it is stated by Louth, in 1831, it is stated by Louth, that the greatest part of the country is forested; the remainder is meadow and field; the people are chiefly engaged in agriculture; and though the farming is not extensive, it is conducted with great attention and success. The town of Wicklow, the seat of the Catholic bishop, is one of the most ancient towns in Ireland. It comprises 2,193 acres, of which 1,942 acres are meadow and field; and the land is chiefly devoted to grazing. The town is situated on the left bank of the river, which is called the River Frest, and is navigable for small vessels. The town is surrounded by a strong wall, and defended by a moat. The castle and church are ancient, and the town is of considerable antiquity. The town is the seat of the Catholic bishop, and is the chief town of the county.

Surface, Coast-line, Geology, and Scenery. —The county of Wicklow is covered by the mountains which skirt on the south-east the great limestone plain of Central Ireland. The mountains may be regarded as part of an extensive range crossing this part of Ireland in a south-west—south-east direction, and extending from the Barrow and the Suir near Waterford. The central part of the range consists of a mass of granite, having its strike or direction coincident with that of the range, and cutting across the strike of the slate rocks, through which it is bounded by Louth. The town of Wicklow is situated on the coast, 27 miles in a direct line south-south-west of Dublin, or by the mail route through Bray, Delgany, and Newtown-Mount-Kennedy, 314 English miles.

The eastern flank of the Wicklow mountains presents a varied aspect, being worn into deep gulls and dells, which are lined with abrupt precipices or overhanging ledges, from which and the mountain composed of slate and free from metamorphism. The consequence to the south-east is distinguished by the most beautiful and romantic scenery. The western flank, on the other hand, presents less variety; the gulls and valleys, which exhibit fewer features of attraction, being more rounded and expanded. The rivers which arise in these have a general tendency towards a north-west direction; but on both sides of the central range the transverse valleys either merge into or cut across more expanded longitudinal vales by which the central range is flanked, and beyond which arise offsets or detached groups and parallel ranges of lower hills. (Mr. Weaver, in Geol. Transactions, vol. v., p. 123.)

This mountain range cannot be considered as having a clearly defined crest or ridge extending longitudinally, but it is intersected by its transverse valleys, so that the mountains which compose it are separated into two groups, with their principal summits, as are follows:—

1. Prince William's Seat (on the border of the county), 1823 feet above the level of the sea at low-water; 2, Kippure (on the border of the county), 2173 ft.; 3. Butter Mount, 1459 ft.; 5, Dowry, 1060 ft. These are enumerated in the order of their position from east to west. The following are the head of the Dargle: 6, Maulin, 7, Tonduff, North, 2049 ft.; 8, Tonduff, South, 2107 ft.

Group II.—Between the Dargle and the Liffey on the north; the Avon-more on the east; the Avon-beg, which waters Glen-malur, and the King's River on the south; and the King's River at the Liffey, west. 9, Blackmoor Hill, south-east of Blessington, 1464 ft.; 10, Sorrel Hill, 1015 ft.; 11, Black Hill, 1084 ft.; 12, Moan Bank, 2313 ft.; 13, Gravel, 2352 ft.; 14, Duff Hill, 2364 ft.; 15, Mullaghcleevaun, 2783 ft.; 16, Tolnaiaghe, 2307 ft.; 17, South-east of Donore, 2401 ft.; 18, Mountain north of Lough Dan, 2103 ft. The mountains in these two groups are chiefly granitic. Mica-slate is found on the south-east side of Group II., and clay-slate farther to the south-east; clay-slate is also found on the north-west side of the county.

Group III.—Between the Fartary or Vartry and the sea.

19, the hill above Bray Head, 608 ft.; 20, Little Sugar-loaf, 1130 ft.; 21, Great Sugar-loaf, 1631 ft.; 22, Down's Hill, 1222 ft.; 23, hill west-south-west of Newtown Mount Kennedy, 1964 ft.; 24, Hill west of Newtown Curracloe, 1252 ft.; 30, hill above Wicklow Head, 298 ft. Douce is granitic; the hill (No. 26) east of Lough Dan is of mica-slate; Curracloe is of quartzite; see the others in the county.

Group IV.—Between the Fartary and the Avonmore, extending southward to the ocean.

25, Douce or Djoce, near the head of the Fartary, 2384 ft.; 26, hill east of the Fartary, 2730 ft.; 27, hill east of the town, 1272 ft.; 28, hill west of Moneystown Hill, 1408 ft.; 29, Carrickmacreilly Mountain, 1225 ft.; 30, hill above Wicklow Head, 298 ft. Douce is granitic; the hill (No. 26) east of Lough Dan is of mica-slate; Curracloe is mostly of quartzite; see the others in the county.

Group V.—Between the King's River on the north, the Avon-beg and the Ovoca on the east, the Daragh or Derry or Aughrim, a feeder of the Ovoca, on the south; and the Slaney and its affluent the Carrigogower, on the west. 31, Slievenagord, 1242 ft.; 32, Wet Mountain, 1753 ft.; 33, hill near the junction of the Carrigogower with the Slaney, 1023 ft.; 34, Table Mountain, near the head of the Slaney, 2302 ft.; 35, hill south-east of Table Mountain, 2405 ft.; 36, Lugnaquilla, the highest mountain in the county, near the source of the Little Slaney, 3030 ft.; 37, Carrawaystick Mountain, 2211 ft.; 38, Croghan Moira Mountain, 2175 ft.; 39, Slieven Reagh, 1904 ft.; 40, Carrig Mountain, 1845 ft.; 41, quillen and Keaden, 2460 ft.; 42, Greyscaton Hill, or Brus- selstown Hill, 1343 ft.; 43, hill above Cillur- taggart Lodge, 1754 ft.; 44, hill above Preban church (to the north), 1270 ft. The last two hills are between the Daragh or Derry, and its feeder the Ovoca. The district to the west of the mountains is chiefly granite, although a considerable portion on the eastern side is occupied by slate rocks; the part nearest to the granite being occupied by mica-slate and the remoter part by clay-slate. Carrawaystick and Croghan Moira are chiefly granite, with some mica-slate and clay-slate. Hill No. 44 is also slate. Slate-rocks prevail also, but not so extensively, on the western side of the group, where they compose the mass of Brusselstown Hill; and in the granite district some of the mountains, as Lugnaquilla and Keaden, are capped with mica-slate.

Group VI.—West of the King's River, the Carrigogower, and the Slaney. 45, Hill to the north of Boystown or Hollywood church, between the King's River and the Liffey, 1075 feet; 46, summit of Timown, to the right of the road from Kilconlie to Ballinglass. The hills of this group
are of slate : mica-slate on the south-eastern side; but clay-slate in the other parts of the group.

Group VII.—Mountains south of the Daragh and Ovoca. 47. Croaghan or Croghan Kinshela, 1390 feet; 48, summit near the head of the Glendine River, 1320 feet. Generally speaking this district is occupied by clay-slate, but Croaghan Kinshela is formed of granitic and trap rocks alternating with clay-slate.

Group VIII.—Mountains of the barony of Shillelagh, which form a good westward projection from the main part of the county. 49 and 50, hills between the Daragh or Derry, which joins the Ovoca and another Derry, which joins the Slaney, 1316 feet and 1416 feet high respectively. 51, the Slieve na Tionney, 1312 feet; hill west of Shillelagh village, 1381 feet. This district is occupied on the western side by granitic rocks, in the centre by mica-slate, flanking the granite on the east, and on the eastern side by clay-slate.

The Granite which forms the surface-rock of the central district, occupying a tract of varying breadth, from 7 to 14 miles, is the fundamental rock on which the other formations rest, protrudes in isolated portions in the districts occupied by the slates. The granite is in general remarkably pure, and free from minerals not essential to its composition. It varies much in the size of the grain: some of the largest-grained and most beautiful occurs in Glencree, in the northern part of the county, amid the mountains of our first group; some of the finest-grained, remarkably uniform in size, is found in the glen of Imale, on the northern side of Keadeen or Cadeen Mountain (No. 41, Group V.). The granite is not unfrequently porphyritic, as in Glencree and Glen-amaconn. School, tourmaline, garnet, beryl, rock-crystal, epidote, heavy spars, magnetic iron, chlorite and mica, and other minerals are found in small portions. Contemporaneous veins of granite, and less frequently of quartz, are found in the granite mass. Granite of later formation is occasionally found alternating with the rocks which rest on the fundamental granite.

The mica-slate district on the eastern flank of the granite is in general narrow, never exceeding three or four miles in breadth: it generally passes into clay-slate, by which it is bounded on the east side, throughout its course in this county. Hornblende and hornblende-slate-greenstone, quartzite, felspar, tourmaline, beryl, amphibole, epidote, quartz, mica, chlorite, and other minerals are found in small portions. Contemporaneous veins of mica-slate, and less frequently of quartz, are found in the granite mass. Granite of later formation is occasionally found alternating with the rocks which rest on the fundamental granite.

The mica-slate district on the eastern flank of the granite is in general narrow, never exceeding three or four miles in breadth: it generally passes into clay-slate, by which it is bounded on the east side, throughout its course in this county. Granite of later formation is occasionally found alternating with the rocks which rest on the fundamental granite.
southward the cliffs subside, and a shelving shore succeeds for a mile and a half, until a small headland, the Grey Stones, presents another range of low cliffs, only half a mile long, which are very soon replaced by a low shelving shore extending ten or twelve miles south to the mouth of the Vartry, or Fartry, at the town of Wicklow. Here the cliffs (which in one place are 69 feet high) reappear, and continue for two miles to the neighbourhood of Wicklow. Elevation: The upper banked bed is a deep broken shore, which extends for seventeen or eighteen miles to the southern boundary of the county to the stream which separates it from the county of Wexford, interrupted occasionally by low cliffs, and sometimes skirted by sandhills or rough ground. There are the ruins of a castle along the coast to the south of it. Brittas Bay is bounded on the north and south by small headlands, with low cliffs. The southern headland is called Mizen Head; and a ruined tower on the hill, in the side of which the cliffs are formed, is only two feet above low-water mark, and the face of the cliffs is still lower. The cliffs are of the clay-limestone formation, which occupies the whole coast. The mountain which rises above Bray Head is of quartz rock. The whole length of the coast may be estimated from thirty-five to forty miles in all. The only harbours are formed by the mouths of the rivers Dargle, Vartry, and Ovoca, and they are all unimportant.

The scenery of the county of Wicklow is pre-eminent for its glens justly celebrated for their remarkable beauty, with dark cleft or hollow, between two mountains, the sides of which are richly wooded, is a much admired spot, and, owing to its nearness to Dublin, is much frequented. The little river Dargle, which flows through the glen, is formed by the union of the Glen-dasan and the Glen-done-lasane, which latter waters the ancient demesne of Powerscourt (the residence of Lord Powerscourt), in the deer-park of which it forms a beautiful waterfall. The直流 falls over a perpendicular rock at an elevation of 300 feet: it is a mere stream, but its fall is very striking from the rich verdure of the surrounding scenery than from the volume of water. The appearance is most striking when a heavy fall of rain has swollen the stream.

The Glen of the Downs is a romantic opening between two mountains, the sides of which are covered with rich hanging woods, interspersed with rugged cliffs. The glen is watered by a small stream flowing into the sea near the village of Delgany, and is partly comprehended in the beautiful demesne of Belvedere, the seat of Mr. G. Moore. It is surrounded by the picturesque form of the Great Sugar-loaf Mountain, the conical summit of which, viewed at a distance, appears to terminate in a peak, but is found, on attaining it, to be crowned with a small flat plain, commanding a noble view of the sea.

The Devil's Glen is a narrow pass between two mountains rising precipitously on each side of it, and has little more than five miles, with passages for the river Vartry, which forms a united stream in this scenic direction. The northern side of the glen is occupied by rich woods, with masses of rock occasionally breaking through the foliage. The southern side is comparatively bare of wood, but the rugged face of the rock is relieved by patches of green-awn, some of them planted with forest trees. The two sides of the glen present in their geological structure and appearance a marked correspondence. The glen, from its depth and narrowness, is dark and sombre in its character. At its upper or western extremity is a noble waterfall: the Vartry falls in a sheet of water, about thirty feet long, from one hundred and sixty to two hundred feet high in one unbroken sheet into the hollow beneath, and presents, particularly when the stream is swollen by rains, a spectacle of great magnificence.

Glen-da-lough, or Glen-anamnas, is a valley amid the higher mountains of Belvedere House, a curved precipice partly incloses a vast hollow into which the river Avonmore (which waters the valley) falls over the brow of the precipice. Above the waterfall at some distance rises the lofty mountain Tompleyage, the sides of which present many bold granitic precipices. Under one of these precipices, from 400 to 500 feet high, is the small circular lake or tarn Ober, at an elevation of 1828 or 1830 feet above the level of the sea. The military road made after the insurrection of 1798 ascends this precipice. The valley of Glen-da-lough is watered by the Glen-ealo (apparently a variation of the name Glen-dalo), i.e. Glen-da-lough, the valley of two lakes), which joins the river Glen-danass, and falls with it into the Avon-more. The valley extends east and west, is inclosed on the north and south sides by lofty, barren, and inaccessible mountains, which unite and close the western or upper end of the valley, presenting granitic or mica-slate precipices 500 feet high. The river tumble over the rocks at the west end so as to form a cascade, and then expands into two streams, over a mile wide, which are separated by a quarter of a mile wide, and range 440 feet above the level of the sea; the lower lake is about 435 feet above the level of the sea, only about a quarter of a mile long, and about half that distance wide. Adjacent to this lake, at its lower end, are the ruins of a church.

Glen-danass, or Glen-anamnas, opens into the valley of Glen-dalough, or rather the three valleys, Glen-amacnass, Glen-danass, and Glen-dalough, all open near the same point into the wider valley of the Avon-more, which should be regarded, with reference to its direction, as a prolongation of Glen-amacnass. Glen-danass is inclosed on both sides by steep and lofty hills; near its upper end is the lake or tarn Nabangass, half a mile long, and nearly as much wide, about 1899 feet above the level of the sea, and having on its south side precipices rising 300 feet above the margin of the lake.

Glen-malur, or Glen-malure, is to the south-west of the last valley, and nearly parallel with the former, and is a south-eastern direction, having the Table Mountain (Group V., No. 34) at its upper or north-west end. The mountains rise with considerable steepness 600 or 800 feet above the valley, and more than 2000 feet above the level of the sea. To the south of the table is the ruined castle of Glen-amacnass, the last of the valley, but not immediately adjacent to it, 2500 feet above the bottom of the valley at the lead-works, or more than 3000 feet above the level of the sea, having at its top a large flat stone resting on low supports, somewhat like the table of the Druids. The west side of the vale of the glen is a waterfall formed by the Avon-beg (or, as it is called in the upper part of its course, the Eos), which waters the valley. The fall is broken by projecting crags, and loses itself in a succession of rapids in the hollow northern. Very different from the latter is the Avon-beg itself. The Dargle and the Downs, Glen-malur is characterized by the absence of trees; and this circumstance imparts to it an air of peculiar sterility and desolation. There are lead-mines in Glen-malur, and its mineral treasures have given it the name of the Gold Coast. The Avoca, or Ovoca, is a rapid stream rolling over a rocky bed. The Avon-more has a gentle current. Castle Howard is a modern building in the Gothic style, but of somewhat incongruous architecture, combining the castellated with the monastic character.

The picturesque beauties of the Vale of Ovoca, or Avoca, have been celebrated in Moore's 'Irish Melodies.' In his song 'The Meeting of the Waters' he has commemorated the junction of the Avon-more and Avon-beg, which unite to form the Avoca. Mr. Moore speaks of the junction of the 'rivers Avon and Avoca.' This, if we may trust our other authorities, is not correct. The name Avoca, or Ovoca, is not given except this place the expansion of the valley at waters are both called Avoca, one the Avon-more (or Great Avoca) and the other the Avon-beg (or Little Avoca). The scenery near the point of junction is improved by cultivation: the grounds of Kingston House, Mount Avon, Avoca Cottage, and Castle Howard, add to its beauties. The Avon-beg is a rapid stream rolling over a rocky bed. The Avon-more has a gentle current. Castle Howard is a modern building in the Gothic style, but of somewhat incongruous architecture, combining the castellated with the monastic character.
Hydrography and Communications.—The central mountain-ranges divide the county into two slopes, the eastern and the western. The first is drained by the Dargle, the Vartry or Fartry, the Three Mile Water, the Potter's River, and the Ovoca: the western by the Liffey and the Slaney, with their respective affluents. These two last-named rivers, although distant from each other, afterwards turn eastward, and passing through openings in the mountain-range, fall into the Irish Channel, as well as the rivers which drain the eastern slope.

The Dargle (11 or 12 miles long) rises to the north-west of The Curragh, in the Partry Mountains (No. 25, Group IV.), and flows first east, then north, then north-east, into the Irish Channel below Bray. In its upper part, above the junction of the Glen-cree, it is called the Glen-isl/orane.

It receives the Glen-cree (7 miles long), the Cookstown (7 miles), and a small stream from the precipitous side of the Scalp (5 miles), all on the left bank. This last stream, and below its junction, the Dargle itself, forms the boundary of the counties of Wicklow and Dublin.

The Fartry, or Vartry, rises on the eastern side of Douce Mountain, and has a course of 18 miles, first east, then south, then south-east into the Irish Channel, below the town of Wicklow. It waters the Devil's Glen. It approaches very near to the sea, about two miles north of its mouth. It has, moreover, from being passing near the ridge of sand or beach which here lines the shore, expanded into a narrow lagoon above 2 miles long, called 'Broad Lough,' at the southern or lower end of which it flows into the sea. The long tongue of land intercepted between the lagoon and the sea, is called the called the Devil's gap, or Murnah, and is partly occupied by the Wicklow race-course. The Fartry receives no tributaries worth mention.

The Three-Mile Water has a course of 6 miles, and the Potter's River of 7 miles, and are joined by the junction of the Avon-more (22 or 23 miles long) and the Avon-beg (15 miles). The Avon-more rises on the south-east slope of Duffhill (No. 14, Group II.) and passes through Lough Dan; it receives on the left bank the Annamoe, which rises in Crocken Pond (7 miles), and flows 1720 feet along the side of the slope, has a course of 6 miles, passing through Lough Tay, an oval lake the longer diameter of which is above half a mile, elevated 807 feet above the level of the sea, and surrounded by steep, abrupt, and wooded heights. The Avon-more also receives also the rivers which respectively drain Glen-anamnae, Glen-dasan, and Glen-dalough: the first has a length of 8 or 9 miles; and the third, which is called the Glen-sallo River, of 5 or 6 miles; the second, which joins the Avon beg, has only a course of 4 miles. Lough Dan, through which the Avon-more flows, is nearly 2 miles long from north-west to south-east, and about 3 furlongs across at the broadest part; it is about 680 feet above the level of the sea. Lough Nahanan (5 miles long), and the Upper and Lower Lahoury, or Lough dalough, have been described. The Avon-beg receives no tributaries of importance. From the junction of the Avon-more and the Avon-beg the river now called Ovoca flows 9 miles into the sea below Arklow, receiving on its right bank the Daragh, or Derry, or Aughrin (16 miles long), into which the Gold-mine River (4 miles long) and the Ow (10 miles) both fall. The Ow rises on the eastern slope of Lugnaquilla (No. 36, Group V.). The whole length of the Ovoca, measured from the head of the Avon-more, is about 34 or 35 miles.

The Liffey rises in a bog near Crocken Pond (from which the Annamoe flows) and has a course of 19 or 20 miles, first north-west, then south-west, (partly within and partly upon the border of the county), to the place where it meets the river Liffey, a river of the mountain-range, which it chiefly belongs. It receives the King's River, which rises on the south-western slope of Tonelagee (No. 16, Group II.), and flows first south-west, then west, then north-west, and flows 6 miles into the Liffey through Blunden and Ballymore Eustace, receiving in its course a number of small streams, none of them more than 4 or 5 miles long.

The Slaney rises on the northern slope of Lugnaquilla, and flows in a winding channel, 12 miles west to a little below the junction of the Carrigower: it then turns southwards, and flows 6 miles by Baltinglass into the county of Carlow, to which county, and to the county of Wicklow, the lower part of its course belongs. Its whole course, in the county of Wicklow, is about 18 miles. It receives on the left bank above the bend the Little Slaney (6 miles long) from the western slope of Lugnaquilla, and the Carrigower (6 miles long) from the north-west slope of Sliheen Gadoe (No. 31, Group V.) on the right bank. The Derreen, a feeder of the Slaney, which it joins in the county of Carlow, has its source and the upper part of its course in this county. It then flows through the districts of Glen-macnass and Glen-dasan, and sometimes flows through the southern part of the county. The affluent of the Slaney, known in different parts of its course as the Green-inland, Slisheen LAW, island, or Derry river, has its source, and a considerable part (10 or 20 miles) of its course, within or upon the boundary of this county: in which it joins the river of the county. The affluent joins the Slaney soon after quitting this county near Clongeal on the border of the counties of Wexford and Carlow.

Most of the lakes have been noticed in connection either with the scenery or the rivers. Upper Lough Bray and Lower Lough Bray are mountain lakes in which the feeders of the Glen-cree have their respective sources; the first is 1453 feet above the level of the sea, and has a basin of 25,620 acres, and the second is above the level of the sea, and has an area of near 65 acres. They are near each other and are skirted on the west by steep and precipitous rocks on the upper slope of Kippure Mountain (No. 2, Group I.). There are seven small lakes in the north-western part of the county.

The communications of this county were formerly very deficient. The great central range of mountains was passable only at three points, within the county, viz. at Sally Gap, at the head of the Liffey; at Wicklow Gap, at the head of Glen-dasan; and in the same part of the county. In the last second of these passages were scarcely practicable even in summer. This difficulty of communication rendered the part of the county a comparatively secure asylum for the fugitives after the suppression of the insurrection of 1798, and a part of the line of the light-house from Wicklow to Dublin, to which effect it was particularly available for a considerable time. Since that period the whole of the mountain district has been rendered accessible by the construction of an excellent military road, which enters the county on the north, near the head of Glen-dasan, and runs southward and by the Lower Lough Bray through Glen-anamnae, and across Glen-malar, to Asphavanagh Bridge on the Ow. The Dublin and Wexford mail-road enters the county on the north side at Bray, and passes through Delgany, Newtown, the town of Ashford, Bridge, Rathdrum, and Arklow into the county of Wexford. A branch road from this in the neighborhood of Ashford Bridge leads to Wicklow. One of the roads from Dublin to Carlow passes through the county of Wicklow, near the town of Slane, and Baltinglass. The other roads have been improved very much of late years, so that a horse can convey three times the quantity of produce to market which he could twenty-five or thirty years ago. There is still however want of new roads in many places and of the improvement of existing ones. The tillage of mountain-farms has been seriously impeded by the want of roads.

There is no water-carriage in any part of the county, except on the coast.

Statistical Table: Area and Condition of the People.—The following statements from the evidence collected by the Commissioners for inquiring into the state of the poor in Ireland, relate to the barony of Upper Tallbotstown, which includes a portion of the central mountain district of that county, and extends to the north of the town of Baltinglass. It is probable the statements are mostly applicable to the county in general. The barony comprises about 42,928 statute acres, or 62,510 statute acres, of which perhaps 12,000 to 15,000 acres are uncultivated mountains. The mountains are generally composed of "green flag, quarz, stone, in large blocks underneath, and smaller pieces near the surface, covered with a small depth of moor or peat, 2 or 3 feet deep." The soil of the lowland is usually a rather light black mould, with a subsoil of gravel or sand, and sometimes of yellow clay. The quality varies much, but is generally good. Most of the mountain land is dry, and much of the lowland...
but the foot of the mountains and a large extent of bog and moorland are much in want of draining.

The farmers of the district and chiefly small dairy or breeding farmers; some of them pursue to a considerable extent the business of 'vealing,' or of fattening calves for veal. The farms are of all sizes, but most commonly of 30 or 40 acres; and about one-twentieth in mountain farms, or one-fifth in the lowlands, is held in tillage. The dairies are of from 5 to 20 cows; the system of management pursued, whether in the mountain or lowland districts, is nearly the same, but the produce varies considerably. The milk is much greater a measure than formerly, partly from a great extent of waste land having been reclaimed, and partly from improved cultivation.

The rotation of crops is very good; it is commonly as follows:—Oats are grown in the first year after breaking up the grass-lay; in the second year, potatoes, manured; in the third year wheat, barley, or oats. Sometimes the land is laid down in grass immediately after this rotation; sometimes not until another crop of potatoes and another of corn have been raised. Clover or grass seeds are usually sown for the crop of corn, and the land then left under grass from four to twenty years. Clover is cultivated to a considerable extent, and some tresses and trefoil are grown by the larger farmers. One or two gentlemen grow turnips or mangai wuzel, but only to a small extent. In many of the smaller lowland farms, the grass, well, is well suited to them. The peasantry have little or no knowledge of the advantage of an alternation of crops; and do not cultivate the artificial grasses, except clover, which some of them are beginning to grow. The rotation of grasses and land sheep is common, and many parts of the farm in succession, except in the wet or moory bottoms, and in the sheep-walks, which form a large part, if not the whole, of a mountain farm. Little or no follow is made, and very little corn commonly grown after potatoes.

The mutton used for dung, procured chiefly from the farmer's own stock, lime, and peat, or, as it is called, 'bog-stuff.' The use of lime is increasing, though there is none dug in the county, except limestone gravel; the lime is bought in open boxes to be burnt to forty shillings per cwt, which is the usual proportion. The use of 'bog-stuff' mingled with dung, ashes, or other refuse of the house and yard, is fast increasing, especially for the potato crop.

The farmers all plough with two horses, and use Scotch ploughs on the lighter loughs of corn construction and other modern implements are used. The 'fack,' a very strong spade of long, narrow, and almost pointed shape, like an English draining spade, is the only implement employed in mountain ground: it is well adapted to strong roots and hard grund.

Seeds wheat is usually limed and pickled, in order to avoid smut; and the crop is weeded, but very imperfectly, in June. The farmers are generally careful as to the time of reaping their crops, but some let them stand longer than the others. The peasantry frequently incur loss by neglecting to cut their own crops in time, while labouring for hire.

Corn is generally threshed immediately after harvest to pay rent and other expenses. The growth of potatoes has been much extended since the tithe composition, and from the quantity of land which the improved method of farming has afforded facility for bringing into cultivation; but they are never grown for sale. The peasantry always keep the potatoes.

The small farmers grow 'cups,' a kind of potato combining productiveness and goodness of quality; the labourers grow 'tumpers,' which have no merit but productiveness. The refuse, or small potatoes, are kept for pigs or fowls.

The dairy system, which is found for the most part in the extensive mountain tracts which the county presents; and there are hundreds of families who would gladly undertake to bring them into cultivation, if allowed to do so, on condition of being rent-free for a certain number of years, or of being paid a certain sum per head, in aid of their labours. In some parts, under some landlords, this extension of cultivation has taken place, and patches of potatoes, oats, and pastures are found on the very tops of some of the mountains.

The farmer's feeding land: the grass land is used only for dairying or rearing stock, except on one or two large farms. By the introduction of green crops for feeding, the same quantity of land would rear or fatten a greater number of cattle, and give employment to a much greater number of persons. A great improvement has taken place in the cattle stock by the general introduction of the Durham or short-horned breed. Excellent half-bred stock is seen even on the smallest farms, and beautiful thorough-bred animals upon the land of several farmers in the parts of Wicklow, Kildare, and Carlow counties, which adorn the barony of Upper Tallowtown. Sometimes a hundred head of half or thorough-bred Durham cattle have been seen at one fair, and have fetched high prices; persons coming from various parts of England and Ireland to buy them. Indeed it is only the high prices obtained for the young and choice stock of cows and bulls, and the heavy rents they do. On the mountains the native cattle are kept, as being more hardy. The butter made is sent chiefly to Carlow market, where it is considered to be of first quality. It is packed after each churning, when they have sufficient milk to fill a May at once, but have few enough for this, they usually wait for two or more churnings before packing, in order to have the contents of the firkin of the same colour. There is little or no cheese made, the farmers只 produce annually a cwt. of butter, besides rearing a calf.

Few sheep are kept on the lowland farms, but a great number on the mountains. The large old Irish breed, improved by crossing with the Leinseers, are kept in the valley, and the fat sheep, weighing fully 90 pounds per quarter: it is not so high on the legs, but is heavier in the carcass than formerly. The sheep are seldom fattened by the farmers, but are sold to graziers for feeding at a year and a half or two years old. The fleece of the mountain sheep is very useful, and is a chief source of wools for wethers. The native mountain breed, either indigenous or long since naturalized, is kept on the mountain farms: it has been of late years much improved both in shape and wool by crossing with English breeds. A cross between the south-down breeds and the mountain sheep is the Orkney, which, besides being become much more popular, is of high wool. It is thought that the Leinseers should be crossed with this breed before it would be possible for the Leinseers to be raised. The sheep are much smaller than the lowland, weighing only about fifteen pounds the quarter, and the price is about three pounds for eves and four pounds for wethers. They are sold, either from the farms, or from the lowland farms, and are then sent to lowland farms till the following May, at a charge of from 4s. to 5s. a head for wintering. The stronger wethers are however kept on the mountains during the winter in case of very stormy weather. Good mountain land will feed in the summer months three sheep on every two acres. The wethers are sold to the graziers at four years old. Small farmers seldom keep sheep except on the mountains, where they have a few.

The pigs are generally killed when young, large boned, and coarse. Few are bred; they are commonly purchased out of the Connaught droves, the farmers finding this plan more profitable than breeding them. They are killed for bacon, in which a considerable trade is carried on.

In the management of the dairy there is great negligence. The room appropriated for it usually adjoins the kitchen; or if there is no convenience in the house, one of the best of the outhouses is appropriated for the purpose. One farmer who had a dairy of fifty or sixty cows, the English assistant-commissioner found had removed his dairy into a corner of his kitchen, while he was threshing in the outbuilding, which he called his dairy, but which was much more fit for his cow-house. In the dairy of another the ceiling was so high that the stalls were in two tiers, with tucks between, and which description, which omitted a mixture of odours that mechanically impelled the fingers to the nose. In fact such is the general absence of the accommodation, cleanliness, and comfort, as is in the cottages, that it is indispensable to successful dairying, that it is perfectly unaccountable how the farmers here can produce butter of so good a quality; and it must arise in a great measure from the excellence of the soil and climate for the purpose. (Connaught, &c., Observations, &c., by John Moore.)

The fences are generally single or double ditches, with furze or quick hedges, but more generally furze: sometimes they are mere banks with a few furze plants on the top. From their imperfect condition they frequently occasion litigation to the owners on account of cattle trespassing. The gardens of the poor are better fenced than the fields of the farmer. There is not much loss of land by useless fences, except in the hands of gentle

Vol. XXVII.—27
men or large farmers, where broad fences are kept up for
ornamental purposes.

Land is usually let by the Irish acre: and the eager
competition for land from the absence of other means
of maintenance for the people has kept rents up unnaturally
high. The rent of tillage land is about 2s. an acre: the rent of con-ace ground is very much higher.
The tenant calculates on his butter for meeting the rent of
one half-year, and on his corn for the rent of the other.
Four-fifths of the land in the barony of Upper Talbot-
town are in tillage: the rest under ditches; but there is no perceptible difference in the con-
tenance of the tenantry and labourers under the two classes
of landlords. Farms are chiefly held under lease for one
life, or twenty-one years; sometimes for three lives or
through the land, because of the desireable one: they pay £2. to 3l., or even 5l. a year for
a cabin and an acre of ground, or for the ground with per-
mission to build a cabin themselves; and from 6l. to 16l. for the grass, hay and straw for the
cow.

A constant complaint of the rest of the farmers and their
wives sometimes keep fowls, and employ themselves in
knitting stockings, chiefly for use in their own families,
rarely for sale. The profit on a pig was estimated, at the
time of the inquiry, at from 20s. to 30s., or perhaps more.

The food of the labourers consists almost wholly of potato-
tatoes; they never have eggs, except when working at a
distance from home, when they perhaps have one egg
boiled with their dinner. The small farmers occasionally eat a few eggs, but sell the greater part
of what their fowls produce; they have sometimes herds of
a little offal pork, and now and then some bacon or
beef. The potatoes are plentiful, and the labourer family
have three meals a day; one of potatoes, sometimes two, and
sometimes only one. In the interval when the old potatoes are
useless for use, and the new crop is not gathered in (which interval
comprehends a month or six weeks in and about the month
of August), potatoes are the chief food of the labourers.

The conduct of the labourer and his family is worse than
in most. The poor have three meals a day; they are kept from starvation only by the aid secretly
conveyed to them by some kind neighbour, who can ill afford
to spare anything, but who suspects them to be in the ex-
tremity of destitution. The amount of relief thus imparted
is very variable: it is generally small, but frequently
wholly inadequate. When the general poverty is aggravated by
the partial failure of the potato crop, the distress becomes
dreadful indeed, and on some occasions, but for the ad-

cance of money by government, hundreds must have died
through famine themselves.

The cabins of the labourers are built of yellow clay and
mud, with stone foundations; or of mud and stone mixed,
or mud alone. Those with one apartment are usually
14 feet by 10; those of two apartments 18 feet by 10. The
walls are generally built of clay and mud, with clay
intermixed generally with straw; sometimes with heath, reeds, or
potato-stalks, with sods underneath. The floor is either the
natural earth, or is covered only with a thin coating of
clay. The cabin, when it is not kept in repair by the
landlord, is so leaky, and in so wet a state, that it is
commonly in a wretched condition. Cabins are usually
damp, from the floor being below the general level of the
ground; and the dampness is increased by pilferings
and the practice of making the hole for the dung-
and refuse from the household there is small. The
best cabins have a large open chimney, the common ones
only a hole in the roof. The windows are small, usually
16 inches by 10 or 12; those in cabins near the towns
are 20 feet by 12. In the cabins of the labourers, when
broken is frequently replaced by paper, wood, har-
straw, an old hat, or a piece of a garment. In the
country the windows have commonly wooden shutters, except in
the poorer cabins, where the window is stopped, if at
all, with straw or old rag. In the less evi-

privies, and very few of them have pipies or any other
inhabitants whatever. The pig, where one is kept, sleeps
in the cabin. The cost of building a cabin is from 3s. to 4s.
for the common ones, and from 5l. to 6l. for the
best. The number of the labourers building his own cabin, has been about
10s. a year less for his land than he would if the cabin
was built for him.

The cabins generally contain a rough bedstead or frame,
propelled up on blocks of wood or stone, or for those
rich with hard beds. The floor is not paved, and other
inmates, if any, sleep on the ground. In the poorest
cabins all lie on the ground. The bedding consists in
the best cabins of a tick filled with stuff; but in the common
cabins the bedding is chiefly of straw or rushes, heath,
fem, or moss, with a piece of backing, a bail wrapper, an old cloak, or other clothes thrown over it. The covering in the better cabins consists of one or two blankets; that is, most always old and thin; often, in others, of a single blanket and quilt; and, in the most wretched, of a coverlet formed of the remains of an old blanket, carpeting, old clothes, or rags, stitched together or separate. The best cabins have three or four clean or good sloots, a table, a small dresser, with a little stock of plates, cups, saucers, and mugs, a few tin vessels and pans and pots for water and cooking, a chest or box or two for clothes, etc., and a tub or two for potatoes or meat. The poorest class have none to little stock, a shabby table, one broken cup or mug, an old tin can or cracked pitcher, and a pot to boil potatoes. Children usually sleep with their parents till 12 or 13 years old, unless the number be too great; when there is a sufficient covering for a separate bed. Only two or three of the younger ones sleep with their parents, but where there is a want of covering, as many as five or six sleep with them. The crowded state of the cabins and the destitution of the inmates perpetually lead to a neglect of the decencies of life, which are less attended to than in some other counties where an equal degree of wretchedness prevails.

The clothing of the labourers is very bad: about one-third of the population who are of age to attend public worship, wear from three to six or eight 'shirts' (from the front of the breast to the waist) without a shirt of any kind. The women and girls, from the cheapness of printed cotton, manage usually to get an outer garment, but are much in want of under-clothing. They have perhaps only one shawl among them, and take it in turn to go to chapel. There is generally the constant feeling of being barely sufficient for decency, and utterly insufficient for warmth. The use of shoes and stockings is decreasing every day among the women and children; the men must have shoes to dig with, but they are commonly very old. Their common fuel of the cottage is turf, which is dear except near the bogs. When the labourers are unemployed, they collect heath and furze, which they cut on the mountain. Many of the proprietors do not permit this, as it diminishes the game of cover. The poorer labourers, whose land is being barely sufficient for decency, and utterly insufficient for warmth, have no other clothing than their old clothes, stubble, or dried dung. Insufficient fuel to counteract the dampness and coldness of the climate is considered to be one cause of the early decline of the labourers' health and strength.

The destitution of the occasional labourers obliges them to resort to many shifts for what are commonly deemed necessities. They wash with rain-water to save soap, and for candles use rushes dipped in fat. Yet amidst all this poverty the greater part of the labourers smoke, and many pock in every family. An assistant-commissioner remarked an almost universal inattention to cleanliness, and what is in other countries considered decency of appearance, both in house and person; but in extenuation of this the want of early training and of all education was stated, and it was suggested that the latter must be taken into the account. Habitual drunkenness is not common; when it does occur, it is found among the tradesmen and small farmers; labourers cannot afford it, and very rarely drink spirits. The farmers drink milk, beer, and, on particular occasions, spirits.

**Divisions, Towns, &c.—The county is divided into eight baronies or half-baronies, as follows. The population is from the census of 1861.**

An examination of this table will show that the population is most condensed in the baronies of Arklow and Rathdown, where it gives rather more than one inhabitant to every three acres, and Shillelagh, where it gives rather less than that proportion. In Newcastle and Upper Talbotstown the proportion is rather more than one inhabitant to every three acres and a half; in Lower Talbotstown it is rather more than one to every six acres; but in Ballincollig, rather less than that proportion. The least populous districts are overspread by mountains; but it is remarkable that Rathdown and Shillelagh, though among the most populous, are mountainous also.

The county of Wicklow contains the county-town of Wicklow, the market-towns of Arklow, Ballyntegal [Arklow; Ballyntegal], Blessington, Bray, Carnew, Dunlavin or Dunlavin, Rathdrum, Stratford-upon-Slaney, and Tintern or Tinnerly or Tinahely; the post-towns of Anna- ghy and Forrestown, Donard, Delgany, Newtown-Mount-Kennedy, and Newbridge; the former city of Glendalough or Glendalough; the decayed and disfranchised borough of Carysfort or Carnesfort; and the villages of Bollinlea or Bollinlea, Donard, Kilcoe, Rathnew, or Newrath, and Red-cross.

The county-town of Wicklow is partly in the parish of Kilpoole, partly in the parish of Drumkay, both in the barony of Arklow; and partly in the parish of Rathnew, in the barony of Newcastle. Wicklow is supposed to have been occupied as a naval station by the O'Connors or Donnachs before the Anglo-Norman invasion; and some would derive its name (which was antiently written Wykinglo, Wy- kenloe, or Wykinglogh, and is interpreted to mean 'the lake of the north') from the district of the county. The Anglo-Norman invaders, beginning to build a castle here, but it was not finished at that time. In A.D. 1310 the town was burned by the Irish. In 1375 the castle was put into a state of defence by one of the Fitzwilliams, in whose tenure as lord it was of great importance. The county-town, in the early part of the sixteenth century the castle and town were occupied by the native septs of the Byrnes, but were soon afterwards surrendered by them to the English government. In the civil war of 1641 the castle was besieged by O'Toole, one of the Irish insurgents, but the siege was raised by Sir Charles Coote.

The town is situated on the south-western bank of the river Vartry or Fartry, along which it extends for above a quarter of a mile. The houses are mostly irregularly built, and the streets narrow and ill-paved. At the north end of the town, on a steep rock or cliff projecting into the sea on the south side of the mouth of the river, are the remains of the castle, called Black Castle. These remains are very trifling: they consist of a rampart including a considerable area, a deep ditch cut or dug in the solid rock, within the rampart and at some distance from it, and a flight of steps cut in the face of the cliffs and leading down to the sea. In the centre of the town are the court-house and the police-station.

The old Roman Catholic church, now (we believe) used for a male and a female school, and the new Roman Catholic church. There are meeting-houses in the town for Methodists and for Quakers. Near the south-east end of the town is an old Roman Catholic church, in a station above the town a post-office and a police-station. On the peninsula of the Murrough or Murragh, on the opposite bank of the river, over which there is a bridge, are a race-course and stand, and some baths. The harbour is formed by the mouth of the river; it is considered capable of being much improved, and made a harbour of refuge for large vessels, at a cost of about 35,000l. Vessels drawing from seven to eight feet water can enter at ordinary tides. There are two lighthouses near Wicklow Head and one half south-east of the town; and on a rocky point (St. Bride's Head) midway between the town and the lighthouses, are the ruins of a Roman Catholic chapel, and near it a cave in a cliff.

The population of the town in 1831 was 2472. The market is on Saturday, for meat, and is held in the market-house which, with the market-place, is in the eastern part of the town. There is no regular market for corn; but the town has the largest corn-trade of any town in the county:
average yearly sale, in the ten years from 1826 to 1833 inclusive, was 450 barrels of wheat, 15,066 barrels of barley, and 21,880 barrels of oats; part of the corn and some copper and lead ore are exported; and coal, culm, limestone, timber, and iron are imported. Four small vessels of from 35 to 100 tons and some small craft belong to the port.

Wicklow was incorporated by charter of 11 James I., and sent two members to parliament before the Union; it was in the patronage of the Tuche family, who received at the Union the

diocese of Dublin and its parishes, and in the

burgh of the same county.

The Union of Wicklow is in the diocese and ecclesiastical province of Dublin. The population was estimated at 10,799 in 1831, and 11,523 in 1834: nearly one-fourth of the population belong to the Established Church: the others are almost entirely Roman Catholics. There are churches and

at Killassery and Glenealy in the Union, with congregations of between 300 and 400, taken together; and a school-house at Rathnew, licensed for service, is attended by 20 or 30. There are the Roman Catholic chapels (at Wicklow, Glenealy, and Killassery), with joint congregations of about 3000. The gross yearly value of the benefice (a vicarage) is 512l. 10s. 8d., the clear value 372l. 11s. 10d. It is in the diocese of Dublin. The rectorial tithes of the Union are assigned to the benefice of Wicklow. The Dublin cathedrals, except a small portion held by a lay impropriator. They were in 1835 twenty-seven schools (twenty-five and two Sunday-schools) in the Union, with 882 children (400 boys and 472 girls) on the books of the day-schools: two of these (with 87 children) were national schools; the others (with 41 boys, 57 girls, and 70 infants, or young children, respectively) were supported by subscriptions; another (with 28 boys and 16 girls) was in connection with the London Hibernian Society; seven others were chiefly supported by benevolent individuals, and the rest were private schools. There was no school for superior education in the Union.

Blessington or Blesington, is in the last-parish of Lower Talbotstown, nearly 16 miles south-south-west from Dublin. The parish is a large area of 15,780 acres 3 roods 7 perches, and had in 1831 a population of 2182, about two-thirds agricultural. The town consists of one street, which, had in 1831, 51 houses, inhabited by 69 families, comprising 426 persons. In the middle of the town the street is widened and forms a market-place. The market-house and a considerable hotel are in the market-place. The church, a handsome modern building capable of accommodating two hundred persons, has a lofty square tower, stands in the churchyard, is about the market-house, and near the parsonage-house and a school-house. There is a police-station in the town. There is a weekly market on Thursday, and three yearly fairs. Immediately adjacent to the town is Blessington demesne, formerly the residence of the masters of the Dublin Union. The sale of serges in 1798, and still remains in ruins. Rusborough house, the seat of the earl of Miltown, Russellstown house, Ballyboys house, and Buggagomoyle cottage, are in the neighborhood in the adjoining parishes of Burgess and Ballyboys. Blessington parish is the head of a union in the diocese of Dublin, comprehending the parishes of Blessington and Burgess, which are united in one vicarage; and the vicarages of Killbride and Ballytown, or Ballyboys. There is a church and school in the Union, but in Blessington and one in Killbride parish, capable of accommodating 100 persons; and three Roman Catholic chapels, one at Killbride and two at Ballyboys. The clear yearly value of the united benefice is 265l. 6s. 9d. There were in the parish of Blessington in 1835, six day-schools, namely by Civil schools and two schools partly supported by the marquis of Downshire; and in the whole Union eighteen day-schools (nearly all of them hedge-schools) with 552 children (300 boys and 252 girls). Blessington has incorporated the charter of Charles II., and returned two members to the Irish parliament; but it was disfranchised at the Union, the marquis of Downshire, the patron, receiving 15,000l. compensation, and the corporation has since fallen into disuse.

The barony of Rathnew, 97 miles west by north of the county of Dublin on the Wexford mail road. The parish has an area of 2955 acres 3 roods 34 poles; and contained in 1831 a population of 3499. The town, or that part of it which is in the county of Wicklow, stands on the south side of the river Dargle, and consists of a long street leading up from the bridge over the Dargle, along the Wexford road, divided at its upper end into two branches, one continuing along the Wexford road, the other leading off to the right towards Bellevue and Kilmacanoge: it contained, in 1831, 412 houses—427 inhabited, 19 uninhabited, and 1 building, with a population of 501 families, or 2580 persons. That part of the town which is north of the Dargle is in the barony of Rathnew, the largest town in that parish and county of Dublin; and had at the same time 227 houses, namely, 193 inhabited, 24 uninhabited, and 10 building, with 269 families, or 1186 persons; making a total in the town of 675, which was named, with 11 building, with a population of 710 families, or 3756 persons. Bray is resorted to as a watering-place, chiefly from Dublin, being recommended by its easy distance and the romantic scenery adjacent to it. The streets are neither paved, nor lighted, but the road is neatly kept, and the houses, though not regular, are neat. Many of them are built and fitted up to be let in the season. The church is near the bridge; and there are in the town a Roman Catholic chapel (besides one in Old Connaught parish, on the Old Dublin road, of the Presbyterian meeting-house, an infant school-house, another building for a school and a savings-bank, a police-station, and a fever hospital, formerly a barracks. The trade of the place is not great; a small manufacturer and baker, and a gentleman, and some coal, timber, slates, and limestone imported, the mouth of the river forming a small haven with a bar at its entrance. There is a brewery and a water-mill in the town. There are two markets, one on Tuesdays and Fridays, and another on Wednesdays and Saturdays. There are fairs in the year, some for cattle, others, which are attended by traders from Dublin, for fowlers. The average yearly sale of corn in the ten years from 1826 to 1835 was 416 barrels of oats; not any wheat or barley. A number of fairs is held about two months before the harvest, and the rest of the year. The population of Bray is 2866; the Wexford portion, of 4073—from two-thirds to three-fourths agricultural. The town is on a crossing road, and consists of one principal street called in different parts Carmel Street and Wolf Green, running directly to the north, and Mill Lane to the south; the number of houses in 1831 was 111, namely, 122 inhabited, 4 uninhabited, and 4 building, with a population of 121 families, or 826 persons. There is a castle which has been built by the church from Dublin to Wexford, but which has since been roofed and repaired. The church is a handsome building with an embattled tower and spire: and there is a dispensary, a post-office, a restaurant, and a school-house for boys and girls. There is a flour mill and a tannery manufactured, there is a school for boys and girls, and near the town, a corn-mill and a stone-quarry. There is a market on Thursday, for pigs, potatoes, and poultry; and there are fairs, four of them considerable; one in the castle, where the houses of Fenners, and it is open the yearly value of 70l. 4s. 7d. There is a chapel-of-ease in the village of Shillelagh. There is a Roman Catholic chapel in the parish. There were in the
parish, in 1835, six day-schools, with 519 children, namely, 263 boys and 183 girls: the four largest schools were all conducted by Lord Fitzwilliam.

Dublin City contains, without the rest of Dublin, in the half-barony of Lower Tallaghtown. The parish extends into the half-barony of Upper Tallaghtown, and consists of two principal streets, the letter T, and consisting in 1831 of 161 houses—155 inhabited, 3 uninhabited, and 3 building; with a population of 365 acres, 2 roads 21 poles, with a population in 1831 of 2529. The town is on one of the roads from Dublin to Timoleen and Castle Domett, and consists of two principal streets, like the letter T, and consisting in 1831 of 161 houses—155 inhabited, 3 uninhabited, and 3 building; with a population of 365 acres, 2 roads 21 poles, with a population in 1831 of 2529.

The market is on Wednesday, for corn and potatoes: the yearly sale of corn on the average of the ten years 1826-36 was 380 barrels of barley and 12,396 barrels of oats; not any wheat was sold. The town is the head of a Union in the diocese of Dublin, comprising several parishes: the clear yearly value of the united benefice is 543l. In the 142, with a glebe-house. There are two Roman Catholic churches in the Union, one very small. There were in the Union in 1831, 622 children, 539 of whom were in 22 schools. These schools had 334 children, namely, 163 boys and 171 girls; one was the parochial school in connection with the London or Hibernian Society, supported partly by a donation from that society, but principally by private subscriptions; it had 366 scholars, and 230 were not supported by the bounty of an individual. The Sunday-school was held in the church, and was for scriptural instruction; it was attended by from 25 to 30 boys and 45 to 60 girls.

Rathdrum is in the barony of Ballinacor North, 23 miles by road, 20 by tack road, from Dublin to Wexford. The area of the parish is 53,155 acres, 2 roads, 22 poles. The population in 1831 was 6263, about two-thirds agricultural. The town is near the right or west bank of the Slaney, about which there is a bridge, and is the most important street from the main street, having in the course of it two large open spaces, one an oval, the other a square, which latter the main streets cross diagonally: there are two or three smaller streets branching from the main street, and leading into the open spaces. The town comprehended, in 1831, 105 houses, namely, 101 inhabited and 4 uninhabited, with a population of 151 families, or 532 individuals. It contains the district church of Rathbran, a neat structure erected in 1825; a Roman Catholic chapel, and a Presbyterian meeting-house. Near the town, on the bank of the Slaney, are a cotton print-work and a bleach-mill; and near the Little Slaney, which falls into the Slaney near the town, is a fever hospital.

Stratford is the seat of a considerable manufacture of printed cottons, which, with the woollen manufacture, employed, in 1831, 177 men, namely, 150 in the town and 27 in the other part of the parish, beside women and children. The market is on Tuesday and Friday. The ecclesiastical district of Rathbran is in the parish (reery) of Baldinglass: the perpetual curacy is of the clear yearly value of 98l. 14s. 11d., arising partly from glebe, but chiefly from an endowment by the late Earl of Aldborough, augmented in 1831. There were in 1835, six day-schools, with 265 children, namely, 160 boys and 125 girls; and one Sunday-school, with 43 children, namely, 20 boys and 23 girls. Of the day-schools, one with twelve boys was a classical school, the rest were here-schools.

Tinahely, or Tinahely, or Tinnahalley, is in the parish of Kilcolman, in the half-barony of Ballinacon South, about 52 miles south of Dublin. The area of the parish is 12,973 acres, about 5400 being arable, 4050 forest, and 3523 waste. The town was destroyed in the insurrection of 1798, and has since been newly rebuilt. It is near a stream flowing into the Green Island or Shillelagh, or Derry river, and consists of three streets meeting in the market-place. There are three houses, nine shops, and 2 to 2 uninhabited; with a population of 111 families, or 375 individuals. There are a considerable water-mill for corn, a market and court-house, a police-station, a post-office, and a dispensary. There is a market on Wednesday, and two or three annual fairs, with two churches, one Roman Catholic and one Presbyterian.

The church is a half mile south of the town, and a Roman Catholic church is a mile to the east-south-east. At Coolcru in the neighbourhood are the remains of a mansion commenced by the late Earl of Stratford. The parish of Kilcolman has a rectory, forming part of the union of Crosspatrick, in the diocese of Ferns: the union is of the clear yearly value of 579l. 6s. 5d. There were in the parish, in 1835, only two day-schools, with 175 children, namely, 71 boys and 104 girls; and 1 Sunday-school, with 476 persons. It is on the right bank of the Avonmore, over which there is a bridge, and has a neat Roman Catholic church, a post-office, and mill. Close to the village is a handsome monument of the late Mr. David Leask.
glen-house, and a school-house. The post-office is a little distant from the village, adjacent to the magnificent demesne of Belveroe, in the Glen of the Downs, the seat of the Lateuche family. Enniskerry is in the parish of Powerscourt, in the half-barony of Rathval, 13 miles from Dublin, on the south side of the Cookstown river, which joins the Dargle. It had, in 1831, 703 acres (69 inhabited and 1 uninhabited), with a population of 98 families, or 497 persons. There are an infant school-house, a police-station, and a post-office. Several respectable families are resident, and the romantic scenery of the neighbourhood renders them attracted to the village of Glenoe, for there are good hotels and lodging-houses. The adjacent demesne of Powerscourt, with its spacious and splendid mansion of hewn granite, is the residence of Viscount Powerscourt. The apartments are vast, and in its large rooms a number of elegant paintings, and the grounds are of almost unequalled beauty. Near Enniskerry are the demesne and house of Tinnehinch, which were purchased by the Irish parliament and presented to the late Henry Grattan as a memorial of his benefactions. The house is in the barony of Newcastle, between 5 and 6 miles from Wicklow. The village had, in 1831, 29 houses (28 inhabited and 1 uninhabited), with a population of 30 families, or 103 persons. In it are the parish church, a Roman Catholic chapel of ease, a national school-house, and a school-house. Newtown-Mount-Kennedy is in Newcastle Upper parish, in the barony of Newcastle, 22 miles from Dublin, on the main-road to Wexford. It had, in 1831, 123 houses (121 inhabited and 2 building), with a population of 520, or 170 persons. It is no longer a market, but it is now discontinued, and the market-house is used for a school-house. There are still several yearly fairs. A chapel-of-ease to the parish church, a police station, and a post-office are in the village; and a large and handsome park is the property of the gentlemen of Dunraven. Newbridge is in the parish of Castlemacadam, in the barony of Arklow. It has been noticed in our description of the scenery in the vale of Ovoca.

Glenoe is in the parish of Derrylossary, in the half-barony of Ballinacor North, 31 miles from Dublin by the military road. The name is properly applicable to the secluded valley already described, in which the ruins of this ancient city stand, and appears to be identical with Gleunoe, or name of the river which drains the valley. In this valley St. Coemgena, or Kevin, or Kevin, a young man of noble birth, born A.D. 408, took up his abode, and afterwards founded an abbey, under the invocation of St. Peter and St. Paul, on the site of which is now described as Abbeyhouse. He died A.D. 618, aged a hundred and twenty, and his festival is kept on the 3rd June. The abbey suffered much in subsequent years. It was burned once or twice by accident, and repeatedly sacked or burned by the Danes or others. No trace of these dispositions in the glen went on increasing, and the jurisdiction of its bishops extended even to the walls of Dublin. About the middle of the twelfth century the religious began to desert the place, and the sea was united, A.D. 1214, to that of Dublin, in the reign of King John; and it is said, as it was affirmed, of the purpose of Cardinal Papillon, papallegate in the reign of Henry II. It is stated in a contemporary record of the union of the two dioceses by the archbishops preserved in Warre's History of Ireland, that the place had been deserted for nearly forty years past, so that 'from a church (says the record) it has become a cave of robbers and a den of thieves: and more murders are committed there, through the lonely and wide solitude, than in all the other places in Ireland.' In the same record the bishop of Glendalough before the annexation is termed, rather slightly, a certain rural bishop ("quemdam coreiscopum"). The see however continued to exist, either by usurpation or papal appointment. The bishops were succeeded by Denis White, last titular bishop, resigned his claims A.D. 1491, and the see has been ever since indisputably united to that of Dublin.

The ruins of many of the ecclesiastical buildings remain. The ruins which are the ruins of the priory of St. Peter and St. Paul, otherwise the priory of St. Saviour, on the south side of the united stream of the Glenoe and Glenadosa; the priory has been a building of more elegant design and richer embellishment than any other building in the valley; but the remains are very imperfect. On the opposite or north side of the stream, a little more to the west, are the ruins of Trinity Church, sometimes called Ivy Church, from its being overgrown with ivy: the nave and chancel remain; between them is a semicircular arch; and there are the remains of a round tower or belvedere joined to the church. A short distance in the west of Trinity Church is a small paved area, said to have been the market-place of the city, with a base of masonry on which the market cross is said to have stood. The market-place is on the northern, or rather north-eastern side of the river Glenadosa, just above the junction with the Glenoe; and though this from the lower paved causeway, the remains of which may be traced in several places, formerly led up the valley of Glen-danas; traces of a road leading up the valley of Glen-dales are on either or both sides. To both these roads the name of ' St. Kevin's Road' is given, and at the end of the market-place the river Glenadosa is crossed by a ford and by stepping-stones: there was antiently a bridge; and opposite to the market-place, on the south side of the ford, are the ruins of the cathedral and of several other churches. The ruins of the cathedral, of what is called the Priests' Church, of a 'Clothetheach' or round tower, and of several crosses, are in an enclosed burial-ground. The remains of extensive due are ministered by a gateway with a semicircular arch. The remains of the cathedral consist of parts of the nave and choir: the nave was 48 feet long by 30 wide, and was united to the choir by a semicircular arch, now fallen down. The semicircular arch of the choir to the north is of excellent moulding, and having on its impost sculptures of some of the traditionary adventures of St. Kevin, and three windows on the south side of the nave, remain: none of them appear to have been glazed; and the east window of the narrowest nave is of a triforium. In the south wall, so that on the outside it is a mere spike-hole. The western doorway is also standing. What is called the Priests' Church, or the Priest's House, is described by Lefebvre as a small and only vestigial structure remains. The crosses in the grave-yard are mutilated: one of them, formed of a single block of granite, and neatly sculptured, is supposed to be the market-cross, removed from its base in the market-place. The round tower is in the north-west corner of the churchyard; 18 feet high, the walls being entire, with a circular band of coping on the top, but the conical roof or cap is gone: the base is 52 feet in circumference; the walls are four feet thick. There was formerly the stump of another round tower not far off. In the north-west corner of the churchyard is a small round tower, or belvedere, covered in with a conical cap rising 45 feet from the ground, similar to those of the ancient round towers. The roof of the church is a high ridged roof externally, rising 3 feet from the ground: at the west end of the church is a small chapel of somewhat later date, with a roof of lower pitch: the chapel was used for worship not many years since. The sites of two other churches may be traced in this area adjoining the churchyard. A short distance westward and northward of the cathedral, but not in the adjacent churchyard are the ruins of Our Lady's Church, a small building of more ornamental character than most of the others, covered with ivy, from which circumstance it is sometimes called 'Ivy Church.' Westward of this church, and on the north side of the valley, are the remains of stone crosses and two or three small earthen forts; and on the south-east side of the upper lake, on the bank of the Lugduff Brook, which flows into it, in the midst of a plantation, are the ruins of a small Church, partly concealed by the growth of the church of the sept of O'Toole. On the south side of the church is a stone with an inscription now illegible, but said to record the interment of one of the O'Toole, who d. A.D. 1853. There are some fragments of stone cross noted this church. On the south side of the same lake are the ruins of another church called 'Templeeniskellig,' otherwise Tayballa-Skellig,' otherwise Dysart-Kevn. Close to the church, in a rocky projection from the mountain which here skirts the south bank of the lake, is an ev
The educational statistics of the same unions and parishes, according to the return made to parliament in 1835, were as follows:—

Wicklow is in the Leinster circuit: the assizes are held at Wicklow, and general sessions of the peace are held there and at Baltinglass. The county-gaal at Wicklow was till lately utterly inadequate in respect of accommodation. For an average of 60 to 70 prisoners (including females and debtors) there were only 32 small cells, 5 day-rooms, 4 yards, a chapel not sufficiently divided and 3 rooms used for an hospital. Large grants have however been made by the grand jury, with the consent of the cess-payers, in order to make the required additions. The prisoners wear a prison dress, and are employed at stone-breaking and net-making, and occasionally at various trades, and a good school is carried on by the turnkeys.

There is a tread-wheel for hard labour sentences. The number of prisoners are closed and dividend-keepers are elected under a matron and deputy, who give them instruction and occasional employment. The whole prison is remarkably clean. ‘The Board of Superintendence meet monthly, and take benevolent interest in the welfare of this establishment; the local inspector is a good man and a religious, and the governor attends to his duty; and the duties of chaplain and medical officer are performed with zeal and attention.’

(Inspectors of Prison Nineteenth Report.)

The county of Wicklow, in the province of Leinster, was also inadequate until within the last two or three years, when an addition has been made to it: there are now 13 cells, 4 day-rooms, 4 yards, with a small hospital, which is room enough for the average number of prisoners, except at session times. It has a keeper, matron, and turnkey; but at the time of the Twentieth Report of the Inspectors of Prisons (Parl. Pappers, 1842) very little in the way of discipline or instruction had been attempted. Some school instruction had been given, but it was doubtful if it had been regular, and there was no chaplain, nor was there any provision for religious instruction.

The criminal returns for 1841 give the number of committals for trial at the assizes or sessions at 254; the number of summary convictions at petty sessions, 112; and the number of persons committed for new trials, 14. These returns were lower in all respects than for any other county. Of 254 persons committed, 131 were convicted, 20 acquitted on capital offences; and 123 were acquitted or discharged.

The county is in the district of the Richmond diocesan in Dublin. The religion is generally Roman Catholic and Baltinglass; fever hospitals at Arklow, Blessington, Bray, Enniskerry, Newtown-Mount-Kennedy, Stratford-on-Slaney, and Wicklow; and dispensaries at Arklow, Aughrim, Blessington, Baltinglass, Dunleary, Enniskerry, Kiltegan, Rathdum, Redcross, Sliehalagh, and Timnehely; and one (locality not given) for Delgany and Newcastle.

The grand-jury presentments for 1840 amounted to 27,065 l. 15s. 2d., thus distributed —

The county constabulary force, on the 1st of January, 1841, consisted of 1 constable-in-charge (second-rate); 47 inspectors (1 extra-rate, 2 first-rate, 2 third-rate); 6 head constables (1 first-rate, 5 second-rate); 29 constables, and...
169 sub-constables (125 first-rate, 44 second-rate); with 5 horses.

But the Union the county returned ten members to the Irish parliament: two for the county itself; and two each for the boroughs of Wicklow, Baltinglass, Blessington, and Carysford; at present it returns only two, namely, the county members. The number of voters on the register at the end of the year 1832 was 1755; the number on the register in February, 1841, was 1603, exclusive of those who had registered in 1832, and had not since re-registered.

History.—Sir James Ware considers this county, and with good reason, to have been included in the dominions of the Cauet (Kassee) of Ptolemy, to whom assigns also the county of Kildare. He supposes them to have been a branch of the German Cauci. The Slaney was perhaps the modern River Mow (Millow) of Ptolemy; and the Ovoca may be safely identified with the Ooboca (Oobes) of the same writer. In the period antecedent to the Anglo-Norman invasion, the barony of Arklow and the southern part of the barony of Newcastle formed the territory of a branch of the sept of the O'Toole; their country was called Crico-Cuaian, or Hy-Briain-Cuaian. Another part of the county, called Imayle, including a part of the mountains-range, belonged to the sept of the O'Toole; and the western part, called Rannilough (a name which seems to be em- bodied in the parish of Rannafast), on the west side of the county, belonged to a branch of the sept of the O'Byrnes. Another part of the sept occupied the east coast adjacent to the O'Kellies.

The church and monastery of Glendalough formed a consti- tuency; the battle attack by the Danes or Ostmen of Dublin, and was repeatedly sacked or destroyed by them. In the Anglo-Norman invasion (a.d. 1169) the combined forces of the invaders and their ally Dermot, king of Leinster, marched towards Glendalough to chastise the O'Toole, in whose country the city stood, and who had refused obedience to him. The city was taken without resistance, and plundered and burned. In the division of lands among the invaders, Wicklow was assigned to Mahony. In the sixteenth century William de Glendalough was lord of the manor of Glendalough; in 1510 he was a freeman of the city of London; in 1563 he purchased the lordship of the Manor of Achidraw from King John, what is now the county of Wicklow was included in that of Dublin, and was not formed into a separate county until the government of the lord-deputy Sir Arthur Chichester, in the reign of James I., A.D. 1605. The native writers appear to have preserved a precarious independence in the mountains; of which the separate continuance of the bishopric of Glendalough for nearly three hundred years after the attempt of the Anglo-Norman government, with the aid of the pope's legate, to convert the region to the Church of Rome, and to restrain them, but with little effect. During the visit of Richard II. to Ireland (1394-5) arrangements were made for the removal of the native septs and for the establishment of English forces in the mountains, but the project was never carried into effect. In the time of Elizabeth, Pheagh or Feagh M'Hugh, chief of the O'Byrnes, was in rebellion against the government. In 1580, in conjunction with his allies, he cut off a considerable detachment of English forces at Glendalough. In 1596 he was defeated, and in 1597 slain. The natives joined in the great insur- renction of 1641, and were in the sequel subdued by Crom- well in his march toward the south.

In the insurrection of 1798, the insurgents of the county alarmed Lord Tyrconnel and Newtown-Mount-Ken- nedy, but were repulsed. The Wexford insurgents entered the county from the south, but were beaten at Arklow by General Needham and Colonel Skerrett; this was one of the most important actions of the war, as it prevented the insurgents entering from the south, and it was the cause of the death of the Duke of York. The insurrections of 1782 were in the north, near Dublin, and the county suffered but little.

WICKLiffe. [Wycliffe.]

WICQUEFORT, ABRAHAM DE, was a native of Hol- land, and was born, it is commonly stated, at Amsterdam, in 1598; but he early left his country and took up his residence in France. In 1626 he was appointed by the elector of Brandenburg his resident at the French court; and he composed that post till 1639. In 1635 he was made Cardinal Mazarin, he was arrested by a lettre-de-cachet, and thrown into the Bastile, on a charge of sending secret intelligence to the government of the United Pro- vinces, and also of being a spy in the pay of other foreign governments. He remained in confinement for a long time and was then released and ordered to leave France. On this he passed over to England, and thence returned to his native country, where the Pensionary De Witt, with whom he had in fact carried on a clandestine correspondence, procured him the appointment of secretaries in the States, or, according to other accounts, of secretary-inter- preter for foreign dispatches. Possibly he held both the offices, or they may have formed only one office. At the same time the duke of Brunswick-Luneburg appointed him his resident at the Hague. It was De Wicquefort's luck however to fall a second time under the suspicion of betraying his trust; in March, 1676, he was arrested and placed in confinement at the Hague, on the charge of being a secret correspondent with the enemies of the States, and in November following was condemned to perpetual imprisonment and to the forfeiture of all his effects. He remained in custody till 1679, when he effected his escape by exchanging clothes with one of his daughters, and fled to Paris, where he lived, however, with that prince because he would not exert himself with more zeal to procure the reversal of the sentence passed upon him by the Dutch government, he left him in 1681. In 1687, he is supposed to have been a prisoner in the island of Jersey. He published a work in 1690, at Paris, in 1659, and in a third edition, which is by far the best, in folio, at Amsterdam, in 1728. This was followed by a translation into French from the Spanish of the embassy of Garcia de Silva into Persia, Ambas- sade de D. Garcia de Silva, &c., &c., Paris, 1667. After his imprisonment at the Hague he published in 12mo. at Cologne a defence of himself under the title of Mémoires touchant les Ambassadeurs, &c., de L. M. P. (meaning, it seems, Le Ministre des Affaires d'Espagne). He translated a letter of the Emperor Leopold to the Prince of Prussia and the Princess of Quenitz, prefixed to a compilation from the papers of the Prince von der Marigny, which he began to write on his return to Holland, in 1659, under the inspection of De Witt. He had both written and printed a considerable portion of this latter work when he was thrown into prison in 1679; but it was first published in a folio volume at the Hague, in 1719. Another posthumous work of De Wicque- fort, entitled Memoires sur le Rang et la Presence entre les Souverains de l'Europe, was published, in 4to., at Am- sterdam, in 1749.

WICKLING, CARL FREDRICH, an eminent practical engineer and writer on hydraulic and civil architecture, was born at Wolin in Pomerania, in 1742. He applied himself so early and so earnestly to the practical study of topography, that when only seventeen he was entrusted with the task of drawing a topographical survey or chart of the duchy of Mecklenburg-Strelitz, which was engraved on nine sheets. His success in this, his first undertaking of the kind, caused him to be employed since early in his career, and to give a complete survey of Pomerania between Belgard and Zamow. From about 1784 to 1788 he was engaged in making similar surveys of their territories for the dukes of Gotha and Saxe-Weimar, and the rulers of some other German states; during which period he also devoted a considerable portion of his time each winter to the study of architecture, as well civil and military as hydraulic and engineering. In 1763 he was appointed engineer in the service of the duchy of Berg, and in 1792 he first appeared before the public as a writer on
professional and scientific subjects, in a work entitled 'Über Topographische Charten,' and his 'Beiträge,' &c., or "Contributions to Practical Hydraulic Architecture and Machinery.' From this time he was chiefly occupied, for many years upon his large work, 'Wasserbaukunst,' to collect materials and information for which he visited Hol-
land, and afterwards France, the latter country together
with his father-in-law, Oberbaurath Rouman, the results
of the researches of which occupied the first volumes of the
following volumes, which were brought out in five
volumes, from 1798 to 1805. This work, which is esteemed
the most complete of its kind, obtained for him a high reputa-
tion not unattended with some advantages, for in 1802
he was called to Paris, in his eighty-sixth year, with an
accession to his income of 2000 florins a salary, and he
was employed to inspect the ports and harbours of Trieste,
Venice, Florence, and other places within the Aus-
trian empire. He returned to Trieste, however, in 1805,
when he was invited to Bavaria, and there became
chief engineer and inspector of roads and canals, which
appointment he continued to hold till 1818, when he re-
tired upon a pension. While actively engaged in his
extensive professional duties, he had not neglected his lite-
rary occupations, one of which was a new edition of his
"Wasserbaukunst;" and now that he was released from the
former, he applied himself diligently to his pen, and under-
took another extensive work of a far more generally
interesting character, his "Theoretisch-praktische Bürgerliche Baukunde," a
general course of civil architecture and its history, in 4 vols.
4to., with a very large folio atlas of plates, 1821-6.

This work is certainly a very valuable contribution to
the literature and science of German Public Works. The
information it supplies relative to the architecture of
Germany, Holland, Poland, Russia, and some other parts
of Europe, in regard to which scarcely anything can be ga-
thered from any other general collection of the kind.
As may be supposed, many of the plates contained in the
first volumes have been often given in various publications,
but there are also a vast many unedited ones, and among them
several original designs by Wiebeking himself. In a work
of so encyclopedial a nature in regard to its subject, repe-
tation is consequently inseparable. The work has been pub-
lished in five volumes. The material contained in the
plates has been greatly bettered, and more
useful for reference, had not the atlas, a huge oblong folio,
opening to an extent of nearly seven feet, been so incon-
tinently large, and quite unnecessarily so, on account of
so many different subjects being introduced into a single
plate. It is also to be regretted that the plates themselves
are inferior specimens of architectural drawing, being, un-
like those in Durand's "Parallèle," executed for the greater
part in such a coarse and loose style, that they are evi-
dently only a "répertoire" of some standing. They are
so incomparably inferior in this respect that the
very great allowance which is to be made for the defects
and deficiencies of a work so comprehensive in its plan as
to exceed the means of a single individual, however well
qualified he may be, is not a sufficient excuse, and which
has collected, and for which he was obliged to depend in
many instances on information received from correspond-
ents, it would now be comparatively easy to improve and
extend what he commenced, and that at a time of life when
most men would be at a loss if they do not extend their
laborious labours. One excellent feature in his work is the his-
torical tables of buildings and architects, drawn up accord-
ing to the respective countries, and although far from com-
plete, and requiring many additions to be made and dates
inserted, it is one of the perhaps more important parts of
his work, and is not likely to be so extended and
exemplified in a separate form.

As to Wiebeking's own talents in architecture, it does
not appear that he ever executed or designed any build-
ings actually erected, a circumstance not particularly to be
regretted, for the works of his first years, which are repre-
sented in the specimens which he has given us, as already men-
tioned, in the work we have just been speaking of; where
one of the designs by himself is for a cathedral, which is
even externally a Corinthian temple, decasyllabic and
perpetrized, discovered however by a range of very lofty and plain
windows within the colonnades; while internally it is in the
Gothic or pointed style. Another design of the same kind
is Gothic within. Greekian Doric in front, and Italian in
character in its side elevations. In others we meet with
large orders applied to façades consisting of several stories,
whereby the windows look as much too diminuitive as the
P. C., No. 1725.
columns do too large; yet, taken independently of the
columns, some of the elevations are of a bold and vigorous
character.

Besides the works already mentioned, he published se-
veral others, his "Theoretisch-praktische Strassenbaukunde," 1808,
and, so late as 1840, one entitled "Analyse Historique et
Raisonnée des Monuments de l'Antiquité; des Edifices les
plus remarquables du Moyen Age, &c." and dedicated to
Queen Victoria of the United Kingdom.
The Chevalier von Wiebeking, as he was usually called,
being knight of several German and foreign orders, as well
as member of nearly all the principal academies and
learned societies in Europe, died at Munich, May 29th,
1842. He was a man of many years, without his
much previous indisposition or the infirmities usually
attending such advanced age. As an instance of longevity
merely, his age is not very extraordinary, but it be-
tween a remarkable degree of useful life which he
credibly maintained, being, namely, that of the family he left at
the age of eighty, and twenty years later, during which
time he was engaged in some useful employment.

The son of these, Carl Wiebeking, is a distinguished engineer, whose first work after his return from France, England, and Italy,
was a bridge near Munich, across the Isar, designed by his
father, and consisting of three arches, each ninety-six feet
in span.

(Endomenosen; Conversations-Lection; Wiebeking, Baukunde.)

WIELAND, CHRISTOPH MARTIN, was born on the
5th of September, 1733, at Oberholzheim, a village in the
neighbourhood of Biberach in Swabia, where his father
was pastor. Old Wieland, who belonged to the Pletzic
branch of the family, was well acquainted with the
ancient languages, and a good philosopher of the school of
Christian Wolf. From Oberholzheim he was transferred
soon after the birth of his son to Biberach, where he died
at an advanced age as senior of the Protestant ministry of
the town. He is best known by his "Berlinische Dinge,
merely, his age is not very extraordinary, but it be-
tween a remarkable degree of useful life which he
credibly maintained, being, namely, that of the family he left at
the age of eighty, and twenty years later, during which
time he was engaged in some useful employment.

matters of taste a very favourable opinion of the young author's talents. It has recently been reprinted in the annotations to volumes of his works. In the autumn of 1750 Wieland went to the university of Tübingen, pro-

fessory to study the law, but he occupied himself chiefly with classical literature, philosophy, and modern poetry, and although his professional studies required as much attention as was necessary to enable him to pass his examination, Socrates appeared to him the beau ideal of a man, and he resolved to follow his example. De Bar's 'Epitres Diverses,' which then caused a great sensation in Ger-

man circles, is said to have been the ten most read volumes ( 'Zehn Moralische Briefe,' Tübingen, 1751), which were addressed to Sophia. These letters, which are distin-
guished for humour and delicacy of feeling, are the best picture of the state of his mind at that time. Another di-
diction, the Anti-Odysseus, a production of a few autumn days, is greatly inferior to his moral letters. While at the uni-
versity Wieland showed little inclination to form friendships with the young men of his own age: his great de-
sire was to become acquainted with the chief literary men, and to engage in the improvement of taste in German.
WIELAND

WIE

ease, gracefulness, and harmonious beauty of its style, which the author himself endeavored to improve by study of the Greek; and a poem entitled 'Die Grazier' ('The Graces'); and a notice on 'Die Grazier' ('The Graces') (1770).

In his novel, 'Der neue Amadis' ('The new Amadis'), Wieland endeavored to show the superiority of intellectual over mere physical beauty: a theme which he took up again in his later years in 'Die Grasier' ('The Graces'), and in his novel 'Die Grasier' ('The Graces') (1770).

In 1756 Wieland married the daughter of a Augsburg merchant, who was devotedly attached to him, and with whom he lived for 35 years in almost unparalleled happiness. She bore him fourteen children in twenty years. In 1782 he paid a visit to his friend Amadis, the duchess of Württemberg, and in 1799 he returned to Germany.

When Wieland returned from the south, he purchased land in the neighborhood of Erfurt. He accepted the offer, and discharged the duties of his office with the most honest zeal, but the envy and intrigues of the academic body, to which he was a disgrace that a poet, and an erotic poet too, should be another Wieland in his way. The secret and open attacks that were made upon him, drew forth the humorous poem 'Der Verklangte Amor,' and 'Nachlaß des Diogenes von Sinope' (1770). The success of these works is the last of his erotic poems, and was written to defend that kind of poetry. The latter was composed to defend his own views of human life and of philosophy. The works which now followed had a more serious and philosophical character, partly in consequence of the political events of the time, and partly in consequence of the changing character of the times, among which we must mention the effects produced by the works of Rousseau, and the reforms introduced by the emperor Joseph II. Wieland attacked the doctrines of Rousseau in a small humorous novel entitled 'Die Grasier' ('The Graces'), in the year 1770. His 'Beiträge zur geheimen Geschichte des menschlichen Verstandes und Herzens, aus den Archiven der Natur' (1770).

Another work, which appeared two years later under the title 'Die Kugel von Scherechian,' was a collection of the poems which the rulers of mankind should derive from history.

Wieland was not at Erfurt long without attracting the attention of the Duchess Amalie of Saxe-Weimar. She was a patroness of the arts, and chose Wieland on the recommendation of Dalberg, and also chose Wieland for the position of Neues Amadis, who was a long-time friend of the Duchess, and who had been invited to Erfurt on the recommendation of Dalberg. The position of Neues Amadis was a great honor for Wieland, and he wrote a letter to Goethe, in which he expressed his joy at the news of his appointment. The letter to Goethe was written in a humorous and affectionate manner, and was received with great amusement by Goethe.

In 1772 Wieland accordingly went to Weimar, where he received the title of Hofrat, and a salary of 1000 thalers, which was continued after the cessation of his duties under the name of pension. The kind and honourable manner in which he was received at the court, the attachment of his pupils, and the intercourse with the distinguished men who were already assembled around the duchess, had such charms for Wieland, that he felt at once that he was in paradise. While in Weimar, he had renewed his acquaintance with Goethe, and edited the 'Deutscher Merkur,' a monthly periodical devoted to criticism and matters of taste. Wieland alone edited it from 1777 to 1784, and from 1789 to 1805 in conjunction with the well-known archaeologist Böttiger. Wieland's own criticisms were on the whole neither true nor profound, and when he expended his principles in his letters on his 'Alcestes,' Goethe and Herder rose in arms against him. Goethe wrote his well-known satire 'Götter, Held, und Wieland,' to which Wieland replied in a humorous and witty manner, and with his usual mildness. This affair drew the attention of Wieland's pupils to Goethe, who was subsequently also invited to Weimar, and became the friend of Wieland. The first important work which appeared after Wieland's death was a new edition of his works, undertaken by the inhabitants of the abbey of Abder ('Die Abderiten,' 1773), which the author intended to be an analysis of the errors, contradictions, and singularities in human nature. It was followed by Erastigen ('Pupils') (1803-1805), a collection of the most interesting works from Wieland's earlier works of fiction by a greater earnestness, depth of feeling, and the absence of voluptuous descriptions. The greatest of all Wieland's poetic productions is his epic romance 'Die Abderiten' ('The Abderites') (1773).

After the publication of 'Oberon,' Wieland abandoned the field of romantic poetry, to devote the remainder of his life to the study of the Greeks and Romans, and he formed the design of making all Germany acquainted with the masterpieces of the ancients by a series of translations. He began with a translation of Horace's 'Epistles' (1782, reprinted at Leipzig in 1816, 2 vols. 8vo., and at Leipzig in 1827, 4th edition), which was followed by Horace's 'Satires' (1790, reprinted 1819, 2 vols. 8vo.). Both works are accompanied with commentaries and introductions, which are useful, especially for the history of the period of Horace. The translation itself is free, and it was intended more for the general reader than for scholars, and is more like a modernization than a real translation. The next production was a translation of Lucian (Leipzig, 1788-91, 6 vols. 8vo.), likewise with a commentary. Took's translation of Lucian of Samosata was translated by himself declared his translation of Horace's 'Epistles' and his commentaries upon them to be his best work, and that from which his own individuality could be best recognized. The multitude of Wieland's long study of Lucian are also visible in the following verse, which is a translation of that writer:—Dialogen in Elysium' (1791), 'Göttergespräche' (1791, 4th edition), 'Geschichte aller Völker' (1791).

Simultaneously with these labours Wieland wrote a great many essays for the 'Deutscher Merkur,' which, when collected, filled sixteen volumes of his works. A collection of all Wieland's works was published at Leipzig from 1794 to 1802, in 36 volumes, and six supplementary volumes, 4to., and great and small folios. All the works of Wieland have been revised and there are many liberal and useful additions to them.

In 1770 Wieland was invited to the court of the Saxon Elector, and he took up his residence there in 1798, with his wife and children, and it was here, in the enjoyment of a quiet and patronage, that Wieland produced all the excellence of his character. He continued however to devote the large part of his time to literary labours. From 1796 till 1804 he alone edited the 'Atisches Museum,' and from 1805 to 1809, conjointly with J. Hootingen and Franz Jacob, under the title 'Archiven der Natur.' This journal was chiefly devoted to the illustration of Greek literature, and here he resumed his old favourite and plan of giving to his countrymen a series of translations of the best Greek writers, of which a great many are contained in this journal. Some original works which appeared before this time contained a series of his renewed study of antiquity, such as 'Aristippus und einige seiner Zeitgenossen' (1800-1802), and the small novels 'Kratas und Hipparchia' and 'Menander und Glyciorion.'

Fortune, which had hitherto always been smiling upon Wieland, threw some of its rays upon an old age. After the death of Sophia Brentano, a granddaughter of Sophia de Leorche, who had been living in his house and had been attached to him as a father, he lost, in 1801, his wife. After this event the retreat of Osmannstadt was no more desolate, and Wieland produced the following inscription, by Wieland:

Lob h E Freundschaft umschließt die verwundbaren Seele im Leben. Und die Friedhofsstecke deckt deren gemeines Grab. —

Love and friendship embrase their kindred souls in life, and this common grave covers their mortal remains. —

342
On the general character of Wieland we may add the following remarks. Wieland was not a poet of the first order; his peculiar talent consisted in appropriating to himself and further developing that which he acquired from others, though he always impressed upon it the peculiar stamp of his own mind. He never penetrated deep into the nature of man, but rather remained in the happy medium by which he is unrivalled in the light and simulating gracefulness of his productions and the elegance of his style. His philosophy breathes the spirit of Socrates, though not without a mixture of the principles of Aristippus. He did not acquire a thorough and lasting influence upon his contemporaries; but his greatest merit consists in the amount of knowledge, taste, and refinement which he diffused among his contemporaries, and which has been transmitted to their descendants. Moreover it must not be forgotten that it was in the work of Wieland which by a massive claim to Germany to the literature of their own country, and who formed a beneficial counterpart to the transcendental character which Klopstock and his school introduced into German poetry.

Besides the below-mentioned works of Wieland's works mentioned above, another appeared in 1819, known as the City of Bohemia. It is situated partly in a fertile plain, partly on several terraces on the declivity of a mountain which forms almost a semicircle around the town. It is gaily built, and contains 470 houses, partly of wood, with 4320 inhabitants. It is remarkable for its celebrated salt-mine, which extends under the whole town and to a considerable distance beyond it on each side; the mine is from east to west 2000 feet broad, from north to south 600 feet, and its greatest depth is 1220 feet. This bed of salt is said to have been discovered by a shepherd named Wieliczka, in 1220, and to have been worked soon afterwards. It is divided into five levels, one below another; according to Baudant, the bottom of the first is 34, of the second 22, and of the fifth 170 toises, or 1020 feet, below the surface. There are three shafts by which they descend into the mine, two of which are within the town, viz., 1, the Leano, with a width of 400 feet; 2, the Danilevich shaft, which is very pure, and only used without any preparation besides pounding; 3, crystal salt, ozkowa sel—this is perfectly transparent and pure, and is used for the table and in the dye-houses; at Wieliczka, crucifixes and small boxes are made of it; 4, bismuth, which, however, is not taken for the crucifixes, but from 450,000 to 500,000 cwt. in a year. The number of workmen is 800 or 900, none of whom live in the mine; but there are 100 horses that always remain under ground. A labyrinth of passages, often connected at a height of 200 feet above the floor, extends through the several stories. In the new chambers pillars of salt are left standing; in the old chambers the roof is supported by timber, which remains in a remarkable state of preservation, the mine being extremely dry, though it contains sixteen ponds, in several of which boats are used. The great chambers made by excavating the salt are used as salt-magazines, coopers' shops, stables for the horses, &c. Sixty or seventy of the chambers are very large, and are chiefly visited by strangers. Those most worth seeing are —1, the great hall, which is very like a vast Gothic apartment, adorned with slender pillars and wreaths of foliage, and a chandelier 20 feet in diameter; 2, the ball-room, which is still larger; it is adorned with a colossal Austrian eagle, transparencies painted on sheets of salt, several chandeliers of the same material, and used ordinary festivities as a drawing-room or ball-room, and when properly lighted has a most striking effect, like a fairy palace; 3, St. Anthony's chapel, in the Gothic style, heated in the salt, with asalt pavement, and life-size; 4, the Corpus Christi chapel; and, 5, a smaller, very elegantly vaulted hall, in which there is an obelisk of salt with a Latin inscription in gold letters. The magnificence and beauty of the vaulted passages, the vast halls, the chapels with their salt altars, chandeliers, images, and lamps constantly burning before them, strike a stranger with wonder.

In the town of Wieliczka there is a mine-office which has the superintendence of the works both here and at the neighborhood; it also cancels the patents of the glass-makers or, as they are called in our law books, Baron and Frene, have been already noticed under their several heads: the mode of contracting the connection may be found under MARRIAGE, and of dissolving it, under Divorce; the process of the action for the violation of marriage is regulated by the common law and modified by statutes, is treated of under DOWER; and the right derived from the same source to the husband to a life interest in his wife's real estate if he survives her and has had a child capable of inheriting, which may be made for the husband, the wife, and the off spring of the marriage, is discussed under SEPARATION AND J OINTURE; and the nature of the property which the wife has, if not independently of her husband, contaminates which may be made for the husband, the wife, and the offspring of the marriage, is discussed under SEPARATION AND J OINTURE; and the nature of the property which the wife has, if not independently of her husband, contaminates...
ties if she suppresses or falsifies the facts. In criminal
prosecutions founded on injuries committed by either party
on the person of the other, the injured party may be a
witness against the other, or a rival in the composition
of law. The property of both is liable to some modifications
liable to the debts of either, and with the person of the
wife the husband takes the liability to her debts contracted
before marriage; but those debts are only recoverable
directly by the other. The only direct claim of the former
from that responsibility, whatsoever fortune he may have
had with her, excepting that he must apply to the dis-
charge of such debts any assets which are received by
him as his wife's administrator. As the law considers the
wife to be under the protection, and by descent of her husband, it
relieves her from responsibility for offences short of murder
and high treason committed at his instigation—the evi-
dence of that instigation being his presence during the
commission of the offence. For the same reason all deeds effect
for her, or committing her property, are void as not being
vested in her or under the guarantee of certain solemnities
to ensure her free agency. A disposition by a woman of
her property after the commencement of a treaty for mar-
rriage, without the privity and concurrence of her intended
husband, is deemed void, and by descent of her husband, it
will be set aside after the marriage as an injury to her
husband; and by the act 1 Vic., c. 26, passed in 1837, a will
made before marriage is revoked by the subsequent mar-
rriage of the party making it. (WILL AND TESTAMENT.)

If a husband, under the eyes of the civil or ecclesiastical courts, by any voluntary
act of the parties. Thus no deed of separation, unless it
contains an immediate and certain provision for the, wife, and
was, with any intention to deprive her husband of any
benefit, a husband from the liability to provide his wife with
accessories fitting to her rank in life ('the question of fit-
ness being decided by a jury'), or consequently from the
duty of paying the debts contracted for such necessities, if
she has been driven from his house by his misconduct.
On the other hand, a wife cannot recover at law from her
husband from whom she lives apart any allowance which he
has contracted with herself to pay her in consideration of
the separation, if he desires that their union should be
renewed. Nor again is there any answer to this suit brought by either party for restitution of
consequent rights; far less is it an answer to the charge of
adultery committed either before or after separation, for
though 'the ecclesiastical court does not look upon articles
of separation as a bar to the property for the settlement,
but they are not brought as to be considered a bar to adultery,'
(Hagg-
ard's Consistory Reports, i. 143.)

This union may be dissolved, when sought for, bond
side, by either party without collusion with the other, as a re-
course to law. The dissolution relieves the husband of his responsibility
for his wife's debts contracted after the divorce is pro-
nounced, or, in case of his wife's adultery, contracted after
the discovery of the adultery and the consequent separa-
tion. The husband in every case, besides in the absence of
cause, and he has given particular notice to the tradesmen
that he will not pay her debts. Still less is he liable for
debts contracted while she is living in open adultery. On
the other hand, where the divorce is obtained by the party on
account of his wife's adultery, that party and the spirit-
ual court continues on him the duty of maintaining her (if
her separate property will not enable her to live according
to her rank in life) by requiring him to make her an allow-
ance proportionate to the property which he possesses,
the right of the husband to her, in such circumstances,
to an allowance under the name of her estovers; and grants her a writ for the recovery of them; but
this remedy is now never resorted to. (For the usual mean-
ing of the word estovers see that article, vol. x. p. 62.)

As to the general and leading principle of the common
law; but this supposed identity of person, of interest, and
of property by no means involves equal rights.

The theory of the law is, that a husband has over his
wife's personal property absolute control, and over real
property a control modified partly by the general rules of
descent, partly by statute, partly by the decisions of courts
of equity, which always lean to the protection of the wife's
property and the maintenance of any contract or provision
made, whether by her husband or others, for her benefit,
so far as to make her liable to the debts contracted by
her next friend against the husband for injuries done by
the latter to her property or for the recovery of rights
withheld by him. To this end they interpret the Statute
of Frauds, as giving the right, by the interposition of trustees, independent rights to property and contracts,
and as the wife's contract with her husband, in so far
although she cannot take by direct grant from her
husband, she may avail herself of such a grant by him to
suits for her benefit, and generally she may take by de-
ferred absolute or real estate, or by order, or by order
through the intervention of trustees; and may hereafter
be a trustee, and (although that position has been contro-
verted) she may devise her trusts. Again, the common
law vests in her husband not only her personal property
enfranchised by the common law, but real leasehold interests; yet if a settlement has not been
made on her expressly in consideration of her fortune, those
portions of her personal property which consist of securi-
ties for money or beneficial contracts, and her chattels
of value, are her property. For the purpose of recovering
the values of property, no suit will lie against her, or her
wife's property, the court will require him to make on her
a settlement proportionate to the benefit which he derives.
Usually one half of the fund is settled upon the wife and
children, but the court takes all the circumstances into
consideration; especially whether any dependent already
exists: and it will not grant its aid to the wife who
demands a settlement, if she is the born subject of a state
which gives the whole property of the wife to the husband.

The too adultery of the wife deprives her of her equity
(unless she has been a ward of court married without the
consent of the court); but her delinquency will not induce
the court to vest the whole of her property in her husband,
because he does not maintain her. The court will secure
the wife's settlement proportionate to the benefit which
her trust property gives her or the proceeds of the trust;
and it is settled only in such a manner as to the legal
person of the wife and her children.

On the other hand, in case of the cruelty of the husband
or his desertion of his wife, the court will award to her and
her children not only the whole principal, but the interest
of the property in question. On the same principle, if the
husband has been unjustly enriched by the wife, she is
entitled to a settlement of property, for the purpose of
enfranchising her interest, by the court. By the common
law a husband might alienate his wife's real estate, or lease it for
her life or that of the tenant, and she was left to her remedy
if she survived him, or her heir at law had his remedy if
the husband survived: if they neglected that remedy, the
court would make good the settlement, and register it in
the name of the wife, or lease it to her, or her children; but by the 32 Henry
VIII., c. 26, the wife or her heir may enter and defeat the
husband's act. By that statute the lease of lands held by a
man in right of his wife, or jointly with her, is good against
husband and wife; and if it be granted without the consent of
her husband; or for life, but it must relate to a premium less
than the interest; if the lease is less than the interest, but not
by anticipation or in consideration of a fine, it must
reserve a yearly rent to the husband and wife; and
the husband is restricted from aliening or discharging
the freehold rent; and thus his interest is protected.
When the husband receives rent after her husband's death
upon any lease of her estate improperly granted by him, she confirms
that lease. A wife's copyhold estate is forfeited to the
lord by any such acts of her husband as are infamous to the
state (e.g. waste), as destroy the tenant (e.g. to convert it into a freehold), or otherwise deprive the lord
of his rights, as a positive refusal to pay rent or perform
service. But courts of equity will relieve the tenant when
the forfeiture is not without or even with the consent
of the husband. A tenement in the wife's copyhold estate by the husband no longer takes the mode of descent, but the estate was
go to the wife's and not to the husband's heirs. Husband and wife to whom freehold or copyhold estates are given or devised take in entirety, and not as joint tenants; so that neither can alienate without the consent of the other, and the estate will be the wife's if she survives her husband.

A mortgage on the wife's real property during their joint lives and during his life in addition, if he survives her and become tenant by the courtesy; if the wife joins in that mortgage, and recognises it after her husband's death, she will be bound by it; but she may, if she thinks fit, repudiate. Before fines were abolished, her levying a fine rendered a mortgage a good security against her and her heirs; and since the act abolishing that form of assurance, a deed acknowledged by her as the act prescribes effects the same object. [Five or Lands.] A mortgage by a wife of her estate for her sole benefit of her husband, and not to discharge a debt of her own, gives her a right at equity to compensation out of his assets.

Such are the principal rights which a husband acquires in his wife's property, and the limitations of those rights. On the other hand, the law gives to her if she survives him an estate for life in a third part of all such estates of inheritance as he was solely seised of during the marriage, and of the remainder of the marriage might possibly have inherited. [Downs.] That right of dower may be forfeited in various ways, and it may be defeated by a provision for her, made before marriage, in the shape of jointure. [Jointure.] Since the stat. 3 and 4 Wm. IV., c. 105, in regard to the exercise of the London, or of any ecclesiastical province of York (excepting the diocese of Chester), if the husband died intestate, leaving personal property more than sufficient to pay his debts and funeral expenses, is entitled to the furniture of his webinar, and his apparel (window's chamber), or to 50L. in lieu of it if her husband's personalty is worth 2000L.; then the personal estate is divided into three parts, whereof one-third goes to the widow, one to the children, and one (the dead man's) to his administrator. In this last share the widow is entitled under the Statute of Distributions, which also regulates the division of it, to one-third if there is a child, and one-half if there is not. The benefit of this custom cannot be taken from the widow by any fraudulent device, such as marriage of the husband to a third party whilst he was at the point of death; or a gift with a reservation at it should only take effect after his death.

Marriage revokes powers of attorney previously granted by the wife, and disables her from granting them; but it does not disable her from accepting such a power, or from acting on one granted to her before coverture. She may too be attorney for her husband. She cannot bequeath her personal estate by will unless under a power, or with the consent of her husband.

The defeasance of the property of the wife has been already treated under that head. [Separate Property; Partition.] There remains one of the most difficult parts of this subject: the separation of husband and wife, and the effect of deeds made by them either before or after the marriage, in order to avoid the temptation of such an event. The ecclesiastical courts consider all deeds of separation and all covenants in the nature of such deeds to be void. The courts of law however not only regard such deeds, but have even caused a deed made by him with his wife, trustees to pay her an annuity as a separate maintenance in the event of their future separation, with the approbation of the trustees. Whether such a covenant would now be supported by the courts of law is very doubtful. In order to render a deed of separation valid it ought to be made by the husband and wife, with trustees for the latter, and any provision made in it by the husband ought to be for a valid consideration, such as a covenant on the part of the trustees to relieve the husband from the wife's debts or maintenance; so the cruelty, or adultery, or desertion of the husband is a consideration, because the wife might have sued him in the ecclesiastical courts, and obtained alimony. But courts of equity will not interfere to enforce such deeds, though by a strange inconsistency they give a moral effect to the contracts of separation, and direct that maintenance may be made if through the intervention of trouble and indeed in certain rare cases if made between the husband and wife alone. Nor is the adultery of the wife a sufficient answer to her claim to the separate maintenance. It is the man's fault who has the power of providing such a kind of allowance; the more so, because it ceases if the cohabitation is renewed, or is only prevented by the perverseness of the wife. The civil law considers the husband and wife as separate persons; and the ecclesiastical courts, following that law, permit them to be used separately.

(Roper's Law of Husband and Wife, edited by Jacob.) WIFE. (Scotland.) The moveable or personal estate of a husband and wife is under the administration of the husband; according to the phrasing of the law it is called 'the goods in community,' because on the dissolution of the marriage by the death of either party it falls to be divided that if there be issue of the marriage a third, and there be no issue at all, goods go to the beggars of the deceased, whether husband or wife, the remainder being the property of the survivor. During the continuance of the marriage the husband's right as administrator is in all respects equivalent to the general right of the husband, the wife has been acquired by himself or by the wife, it is entirely at his disposal, in so far as that disposal is intended to have effect during his lifetime. His right of bequeathing it is limited by the Scottish law of succession. [Will.] As the husband and wife are in the administration of the property responsible not only to the extent of the goods in community, but personally, for the wife's obligations, whether contracted before or after marriage. Action against a wife for debts contracted before marriage is laid against her, not herself, as the habitant of the goods in community, and while all 'diligence' or execution for attaching property falls on the goods in community, he is liable to whatever execution may proceed against the person. In case of the dissolution of the marriage before execution, the execution will proceed only against the portion of the goods in community which falls to the share of the wife or to her representatives, and will not lie against the person of the husband. No suit can be raised against a married man unless his husband has been made a party. The wife cannot enter into a contract or execution by action against the goods in community, and the person of her husband, unless in certain cases when by general law or by practice she holds an agency. To this effect, under the Act of 1813, 1st Geo. IV., c. 25, any debt the wife incurs for household purposes are deemed against the husband. The husband may discharge himself from responsibility for debts so incurred by suing out 'inhibition' against her in the Court of Session.

The sphere of her authority may be enlarged by her husband trusting to her the management of any department of business, and she will then, as ostensibly authorized to represent him in the transactions relating to the business, render him responsible for the performance of her acts as a principal is rendered responsible for those of his agents. A wife's agency will not extend, without special authority, to the borrowing of money.

Heritable property (a term nearly equivalent to the real property in England) belonging to either party by the operation of the marriage is subject to the right of the husband to grant the lease of his wife's heritable property, to last beyond his own life, without her concurrence. On the other hand, from the date of the proclamation of the banish all deeds granted by the husband to himself or his wife for his lifetime are invalid. The right of administration, including the necessity for his concurrence in the wife's deeds may be excluded, either generally or in relation to some particular estate. The former can only take place if the husband has been adjudged a non compos or of marriage; the latter may be accomplished by the special exclusion of the jus maritii in the title of any estate conveyed to the wife. Every deed executed by a wife is presumed to have been executed under the coercion of her husband, and is reducible as a deed executed under the effect of
force and fear, unless the wife ratify it by oath before a magistrate. On occasion of the ratification, not only must the husband be absent, but the act of ratification must be witnessed by two men.

A separation of married parties may take place either by judicial interference or voluntary contract. Actions of judicial separation proceed before the court of session, which in such cases exercises its consistorial jurisdiction as succeeding to the comity courts during the Reformation, and effects physically or morally injurious on the part of the husband, will justify a judicial separation at the suit of the wife. That the husband insisted on retaining a servant with whom he had held an illicit intercourse before the marriage, is in law a reason for a judicial separation. (Letham v. Letham, 8th March, 1825, 2 S. D., 294.)

In judicial separations at the instance of the wife, an alimentary allowance is awarded to her against the husband, proportioned to his means. When a husband abandons his wife, an alimentary allowance will be awarded to her without a judicial separation. A voluntary separation may take place by mutual agreement, but in such a case as alimentary allowance will not be awarded unless it is stipulated for. It is a woman's power, however, notwithstanding a voluntary separation, to sue for judicial separation if the previous conduct of the husband towards her would justify it, and thus obtain an award of alimony. The husband whose wife is either judicially or voluntarily separated from him is under a duty to settle his estate in such wise that no inconveniences may be suffered by her after the date of the separation. Her own property is liable to execution for her obligations, but not her person, unless her husband be living out of Scotland, in which case it has been decided that a wife transacting business in the name of her deceased husband shall, on the discharge of her debts, distribute the property among her heirs. It has also been held, that where the wife is imprisoned for a crime committed by her husband, the imprisonment does not affect her own property. (Orme v. Differs, 30th November, 1833, 12 S. D., 149.) The husband has the uncontrolled custody of the children of the marriage during marriage. The court of session will interfere for their protection in the event of their cruelty or neglect, and in the event of the husband being absent by desertion or danger of contamination, but not on the ground of a special estate being settled on a child by a third party.

On the dissolution of a marriage by the death of either party, the determination of the wife's alimony, and the property is, whether the marriage was permanent. A permanent marriage is one which has lasted for a year and part of a day, or of which a living child has been born. In the case of dissolution by death of a marriage not permanent, there is a question of accounts. It is alleged, that the property of the parties is, as nearly as circumstances will permit, so distributed as it would have been had no marriage between them been solemnised. In the case of a permanent marriage, the movable property is divided as above stated, the goods of the deceased are settled as to her, and the surplus is settled as to her husband. If there is issue of any real property in which a wife dies intestate, if there have been a living child born of the marriage, and if there is no surviving issue of the wife by a former marriage, the widower enjoys the life-rent use; but if there is no issue of the marriage, or if there is issue of the marriage, the life-rent of one-third of the lands over which her husband has died intestate, by way of Tercer. The distribution of the property, personal or heritable, may be otherwise arranged by annulling the contract, or equivalents to the property to which a party would succeed may be made by the settlements of the deceased.

On the dissolution of marriage by divorce (Divorce), the offending party forfeits whatever provisions, legal or consensual, of an inferior or superior privilege; but forfeits to the husband whatever property she may have brought into the goods in common.

WIFE. Roman. [Marriage. Roman.]

WIGAN, a market-town and parliamentary and municipal borough, in the county of Lancashire, is situated at a distance of 18 miles west-north-west of Manchester, and 188 miles from London. Whitaker says that there was a castle at Wigan in the Saxon period, which became the nucleus of the town. Leland's description in the early part of the sixteenth century is as follows:—Wigan, pauid, as bigge as Warrington, and better buildd. There is one place called kimside the town, surrounded with some artificers, and some farmers. Camden describes Wigan as a ' neat and populous' place. The inhabitants showed great devotion to the cause of Charles 1.; the town was several times taken and relented by the contending parties in which the earl of Derby was engaged. The old streets are irregularly built, but some of the new ones have been built within the last century. The town is well supplied with excellent water under an act obtained in 1761, and is lighted with gas by a company formed in 1823. From its situation on the Lancashire coal-field, the population of the borough has increased with the development of the manufacturing industry: it was 5,069 in 1801, 14,060 in 1811; 17,716 in 1821; 20,774 in 1831; and 25,517 in 1841. The manufactures of the place comprise linens, calicoes, checks, fustians, the spinning of cotton, and other branches, and of the manufacture, a most of which a large number of Irish are employed. In 1790 an act was obtained for making the river Douglas navigable from Wigan to the Ribble, which it enters a few miles above the wide-outlet of the Ribble. The shares in the company were purchased by the towns of Leeds and Liverpool Canal, who substituted artificial cuts for the natural bed of the river. The Leeds and Liverpool Canal, which passes through the town, gives it the advantage of water communication with Yorkshire and Lancashire. The Male and Female River, which includes the south-east branch, is navigable for small craft, and connects with other canals near Wigan. The Preston and Lancaster Railway, by which the branch of railway communication is extended from the southern coast of England and London to Lancaster, passes through Wigan. The town of Wigan has received a charter, the first of which was granted by Henry III. in 1246. The governing charter prior to 1835 was granted by Charles II., and under it the municipal body consisted of a mayor, recorder, and forty burgesses. The Reform Act the limits of the borough remain the same; but it is divided into five wards, which collectively return ten aldermen and thirty councillors. The number of burgesses, or municipal electors, in 1837 was 1200. The number of burgesses and other electors was 3285 in 1851. The expenditure for municipal purposes in 1840-41 was 3185l. The principal items of receipt were 141l. for rents and fines; 225l. tolls and dues; 1430l. borough and gaol rates; 300l. from the Treasury on account of the sum of 3437l. paid in 1827, and 1000l. from the borough treasurer. Wigan returned two members to parliament the 23rd Edward I. (1295), and again twelve years afterwards, from that time to the sixteenth century the privilege was not exercised. Before the passing of the Reform Act the corporation paid the poll tax on its non-resident honorary burgesses, who had a right to vote in the election of borough members. The number of this class of burgesses in 1831 was thirty-four. The other electors were residents within the borough, paying a poll tax of forty shillings each, which was previously paid by the burgesses elected at the annual meeting for the election of mayor; this mayor had the power of admitting every male inhabitant resident in the borough of full age to a participation in the election of the burgesses and the mayor, and was the same in the act of 1831 was only 89. The borough had long been notorious for its expensive parliamentary contests. The Reform Act did not alter the limits of the parliamentary borough, which, as well as the municipal borough, was disfranchised by the Reform Act of 1832. The number of electors on the register in 1833-40 was 532.

The parish church of Wigan is a handsome structure. The living is a rectory; gross revenue 2823l., net revenue 2220l. St. George's church was erected in 1791, and was partly endowed by a parliamentary grant; it is a perpetual curacy; gross annual value 142l., net 118l. The Roman Catholics are numerous, and have two chapels, one of which, built in 1818, at a cost of 600l., and another of which, built in 1829, at a cost of 600l. Several thousand dissenters have these two chapels. There is a free grammar-school, founded in the reign of James I.; but by whom it was first endowed is not known: the value of the various
endowments is now worth 2011 a year. Under an act obtained in 1812, fifteen governors were appointed, who elected a head master and usher: the number of boys is limited to eighty. The Blue-coat School, established by voluntary subscription in 1773, for educating and clothing forty poor children, is now united with the national school, in which about three hundred children are instructed. In 1833 the number of children returned as attending the daily schools was 782 boys and 658 girls; and at the Sunday-schools, 2019 boys and 2430 girls.

The town hall was built in 1720, at the cost of the borough members. In the marketplace there is a large brick edifice, 103 feet by 66, erected in 1816, for the use of the manufacturers on market days: it is called the Commercial Hall, but is in fact a cloth-hall. A dispensary was established in 1738, and a building was erected for the institution early in the present century.

The marketplace was opened in 1821, and in 1842 the number of depots was 1628. A mechanics' institute was opened in 1825. The market-days are Wednesday and Friday, and there are three annual fairs.

The parish of Wigan is very extensive, comprising an area of 27,610 acres, or above 43 square miles. The borough boundary contains 2170 acres. There are besides three chapels and eight townships, whose population, in 1811, was as follows:—Chapels—Billinge (Chapel end), population 1550; a perpetual curacy, value 2317; Hindsley, population 5459; a perpetual curacy, value 1427; Upholland, population 3113, a perpetual curacy, value 1097.

The centre of Wigan is the parish of each of the above lives. The townships are—Abraham, population 1981; Billinge (Hilger end), 712; Dalton, 438; Haigh, 1369; Ince, 2555; Orrell, 2478; Pemberton, 4394; Winstanley, 681. The population of the parish (including the borough) was 25,692 in 1801; 31,481 in 1811; 38,318 in 1821; 44,488 in 1831, and 51,688 in 1841. There are several springs in the parish impregnated with sulphur, which have been useful in scrofulous complaints. At Hindley there is a well which takes fire if a lighted candle be applied to the surface. Haigh, Aspull, and Ince are in the same area. At Upholland, Haigh, Ince, Pemberton, and Upholland, 857 labourers were employed in coal-pits in 1831. At Upholland there was once a Benedictine priory, and the priory church is now used as a chapel-of-ease.

(Baines’ Lancashire; Municipal and Boundary Reports, &c.)

WIGEON, or WIDGEON, Anas Penelope, Anas Pene-
lope, Linn.

Description.—Male.—Forehead yellowish-white; head
and neck rusty-chestnut; face dotted with black; throat
black; breast colour of wine-lees; back and sides striped
with black and white zigzags; wing-coverts and lover
parts white; beauty-spots composed of three bands, the
middle white, the two sides green, and the lateral ones
dark black; capillaries black, edged with white; under tail-coverts black; bill blue, but black at the point; iris brown; feet
ash-coloured. Length 18 inches.

Female smaller than the male, head and neck rusty,
sprinkled with black spots; feathers of the back blackishbrown, bordered with rusty; wing-coverts brown, edged
with whitish; beauty-spots whitish ash-colour; breast and
sides rusty; bill and feet blackish ash-colour.

Young Males resembling the females. In very old
male the yellowish-white of the head does not extend upon
the top of the head, which takes place in the males of a year old; it is only in the old males that wing-
coverts are pure white. (Temm.)

This is the Conard Sifflor of the French; Anistra
flecta of the Italian; Pfeifente of the Germans; Stemel, Helv-eend-vogel of the Netherlanders; Wriaat of the Swedes; Ble, and of the Danes; Whoever, Whin,
Prentice, Féc ather, Where, Paivdew, Where, Battering,
and Yellowbell, of the modern British; and Chievie of the
antient British.

Geographical Distribution.—Lapland, where they are
called Great Ducks, Norway, and Sweden, in all which
days they breed; Iceland, where a few breed. Holland,
where they sometimes breed; Germany, France, Spain,
Italy, Egypt.

Habits, Food, &c.—According to Colonel Hawker, the
wigeon either chose their mates or detached themselves into small trips preparatory to that choice about St. Valentine’s day. The nest is placed among bushes, reeds, or rushes near fresh water, and is formed of the two best vegetable materials in a state of decay, with a warm down
lining from the parents’ body. Eggs from five to eight
smaller than those of a Wild Duck, and rich in colour.
A vegetable diet forms the principal support of the wigeon which not only feeds on aquatic plants, but also on
the same kind of short grass as that on which the goose
feeds as Mr. Waterton has satisfactorily proved, in addition
of other evidence of its grazing habits. (Lucas, vol. iv. p. 172.) The last-named zoologist states that the wigeon procures its food in the day; but it is also a nocturnal fowl.

This species has always been in request for the table, for the price in the Northumberland Book which stood against the bird is one penny. Perhaps no wild fowl is so useful to market in greater plenty. Vast numbers are trapped by the decoys; but the ‘gunner’ contributes no share; not so large a quantity however as he formerly. Colonel Hawker truly says that the wigeon for cost of
shooting is like the fox for hunting—it shows the best
sport of anything in Great Britain. No writer has entered so fully or so well on the subject of wild-fowl shooting—the Colonol; and to his good sound practical book we refer our readers.*
The current through the channel, both with the raising and ebbing tide, is extremely strong.

The most extensive ring of chalk downs is that of the Needles Cliff, which consists of 40° of the most fertile land in the island. It is bounded south by the southern range of downs, north by the central chalk ridge west, east by the boundary of the Medina valley, and the sea to the east. The basin of the Medina, which in general very narrows, forms a central valley.

The southerly range of downs is that of the eastern Yar, alluded to above, which comprises a large portion of the most fertile land in the island. It is bounded south by the southern range of downs, north by the central chalk ridge west, east by the boundary of the Medina valley, and the sea to the east. The basin of the Medina, which in general very narrows, forms a central valley.

### Notes
- Includes the hamlet of Kittydarford.
- Includes the villages of Westover, Winton, and Piccott's: the entire parish contains 8777 inhabitants.
- The village of Winton contains 8777 inhabitants.
- This returns 14 persons in the pool.
- The entire parish of Northwood contains 8777 inhabitants.
- This returns 21 persons in houses extra-parochial.
- The entire parish of Northwood contains 8777 inhabitants.

### The chief towns are—Newport, Cowes, East and West, Ryde, and Yarmouth.

### Newport
The capital town of the Isle of Wight, is situated in a valley near the centre of the island, on the west bank of the Medina river, which is navigable to Newport. The tide flows nearly to Newport bridge, and carries large vessels of considerable burthen can ascend with ease. The town is built on an easy ascent, and the streets, which are sufficiently wide, cross each other at right angles. It is a very pretty town, well paved, lighted with gas, and clean. The town-hall and market-house form a neat structure, which is said to be very commodious in its arrangements. It was begun in 1814 and finished in 1816, at a cost of 10,000L. The magistrates of the island meet in the town-hall every Saturday, to determine parochial matters, and to commit offenders for trial to the county assizes. The Isle of Wight Institution, which is a public library and reading-room, is a building which is said to surpass the town-hall in elegance: it was built by subscription in 1811. There is also a Mechanics Institute. The free grammar-school is a large stone building, erected in 1819. The conferences between Charles I. and the parliament were held in the school-room, and lasted forty days. There are two assembly-rooms, and a small but neat theatre. The church
was built in 1172, but has been frequently repaired since; it is a large plain structure. There are six chapels belonging to different classes of dissenters. The House of Industry, in the vicinity of Newport, is a spacious building, with 80 acres of land attached to it, divided into fields and gardens, and cultivated by the inmates; in 1640 there were 14 acres of land, not far from the House of Industry, were built in 1768, and were much employed during the war: they have a good military hospital, and grounds attached to them; in 1840 they contained only 34 persons. Parkhurst prison, for juvenile convicts, apart of an asylum, is situated between the town and the Southsea, a parish, containing, in 1840, 319 individuals, and the gaol at Newport 14. The Lunatic Asylum, which is in Carisbrook parish, contained 34 persons in 1840. Thursday is a market day, and is much frequented by persons from all parts of the island, Newport being a central depot, from which corn and other agricultural produce are shipped, and which imports articles of manufacture, coal, provisions, and whatever else may be wanted for the interior and south side of the island. An annual fair is held on Whit Monday, Tuesday, and Wednesday; and at Michaelmas there are three Bargain-Fair Saturdays, when the country men-servants and maid-servants meet at separate parts of the town to be hired, and this is the great season for rustic sports.

Previous to the Municipal Reform Act in 1832, Newport was a municipal and parliamentary borough. As a municipal borough, it consisted of a mayor, a recorder, eleven aldermen, self-elected, twelve chief burgesses, and a number of common burgesses, incorporated by a charter of James I. The governing charter of the borough was 13 Chas. II. By the Municipal Reform Act it has been divided into two wards, with six aldermen, and eighteen councillors. The number of burgesses is 40; that of electors 126. The 1832 act increased the number of burgesses to 50. The number of electors is 2000. The number of freemen is 5000. The number of electors is 120,000. The number of electors is early as 1304, but did not send them regularly till 27 Eliz. 1564. It was disestablished by the Reform Act.

Yarmouth is a large town. The population of the town and parish, according to the returns for 1841, is only 5673. It is situated at the mouth of the river Yare. It has an excellent roadstead, and there is communication by steam-boat twice a day with Lynn regis. It has a market day, and a chapel, and a Baptist chapel. The town and parish are small.

Newport is a small town. The population of the town and parish, according to the returns for 1841, is 7362. It is situated at the mouth of the river Menai. It has an excellent roadstead, and there is communication by steam-boat twice a day with Liverpool. It has a market day, a school, and a church, a dissenting chapel, and a Baptist chapel. The market-town and town-hall is a small structure. The church is large, and of considerable antiquity. It is a corporation which was not affected by the Corporations Act of 1882. The subscription which is in the right of the corporation is 1 Edw. VI. The population of the town and parish in 1841 was 3277. Boat Haven admits small vessels when the tide is in. Sir Isaac Middleton attempted to reclaim the haven from the sea by windlasses. The town and parish are about 93 miles from London. The market day is a Wednesday.
in the reign of Richard II., but the great cause of its decline was the growing importance of Newport. The municipal body consists of a mayor and an indefinite number of chief burgesses, who are self-elected, and of whom the number in 1837 was 23. The governing charter is one granted in the actual establishment of the borough, and New- town was disfranchised by the Reform Act.

History and Antiquities.—The Isle of Wight was con-
cquered by Claudius, A.D. 43. In 406 it was conquered by Teutonic Saxons, who destroyed the original inhabitants, and appointed Govan by their own coun
ners. In 601 Wysta, king of Mercia, subdued it. Not long afterwards it was subjected and compelled to embrace Christianity by Tredwall. In 787, 987, 998, and 1001, it was plundered by the Danes; and in 1082, Earl Godwin, who had been banished by the Irish Chiefs, plundered it. William the Conqueror bestowed it on 
ismar William Fitz Osborne, and created him Lord of the Isle of Wight. A succession of Norman Lords held 
 until 1449, when Henry V. created Brochurch, earl of 
 the country, which he had conquered, and made himself 
 king of Mercia, subdued it. Not long afterwards it was subjected and compelled to embrace Christianity by Tredwall. In 787, 987, 998, and 1001, it was plundered by the Danes; and in 1082, Earl Godwin, who had been banished by the Irish Chiefs, plundered it. William the Conqueror bestowed it on his kinsman William Fitz Osborne, and created him Lord of the Isle of Wight. A succession of Norman Lords held until 1449, when Henry V. created Brochurch, earl of the country, which he had conquered, and made himself

The title however was not continued, and the last of the Lords was the Earl Rivers, who was beheaded by Richard III. in 1483. During the period that it was held by these Lords it was frequently threatened by the French, but never attacked. When the French were driven away, the Munster of almost the whole descendants was in the reign of Richard II., when they conquered all the island except Carisbrooke Castle, but reduced on receiving 1000 marks from the inhabitants. On the death of Henry VII., Sir Edward Widville, or Woodville, betook himself to the title of the earldom, which lies about three miles from the sea, and the title was held by his successors for a considerable period. The last Captain was the earl of Portland, who was displaced by the parliament, and the earl of Pembroke was appointed Governor in his place. He was succeeded by Colonel Hammond, who governed the island from 1628 to 1641. When the Earl of Clarendon fled to the Isle of Wight after his escape from Hampton Court, he arrived there Nov. 1, 1647. He was not strictly confined at first, but was afterwards, when he made a determined attempt to escape. On one occasion especially, he got his horse, but he would not suffer it to be tied to him, but he drew it back when he found that he could not get his body through. A conference between Charles and the parliament was held in the school-room of the free-lords, and the earldom of Wight came to the parliament. On the 29th of Nov. 1649, he was seized, and conveyed to Hurst Castle. The title and office of Governor of the Isle of Wight is still continued.

The Roman name of the Isle of Wight was Vectis, which persisted as the name of Wight, or Wight, or the county of Wight. In the parish of Yarmouth, about two miles from the sea, there is a church dedicated to those bishops, but there are no traces of Roman forts or camps, or of Saxon warf, Carisbrooke Castle is the only ancient fortress. Its keep is perhaps another to Norman times, but no other part of it. During the reign of the Lords of Wight, whose power and privileges are of the utmost importance, Carisbrooke was the capital of the island, and Carisbrooke Castle was the residence of the Lords. The castle stands on a lofty eminence, and the keep still higher on an artificial mound. Fitz Borne the Norman built the castle, and included the whole tract of land from the sea to the chalky downs, which are about three miles wide. The castle was successively enlarged by subsequent lords. Sir Edward Widville, or Woodville, built the main gateway, which is very handsome, in the reign of Edward IV.: the gate of Woodville appears on its front. There were several other important establishments in the island, but none so extensive as Quarr Abbey, which was founded in 1132. It was dissolved by Henry VIII. It was bought by a merchant from Southam, who swept away everything except some houses of the long walks, which enclosed an area of thirty acres. The abbey has been converted into a no public house, and a few fragments of gables, turrets, and doorways. Carisbrooke Priory is entirely demolished, except the church, which is now parochial. There is a small but very curiously turreted on the summit of St. Mary's Hill. The lower part was probably used as a bury to the church of a hermitage which stood there, and as a part of a lighthouse. It was repaired by Sir Richard Worsley. Some of the parochial churches are perhaps as old as the Norman conquest; some possibly older. Yaverland church is one of the most ancient. The entrance-door is arched, and has what appear to be Saxon moulings of very uncommon forms.

(Voret's History of the Isle of Wight; Sir H. B. Paton, 'The Isle of Wight,' in 'Obe-

In the southern part of the county, and stretches intowards about fifteen miles: the distance between the two headlands of Barrow Head and the Mull of Galloway is about ten miles, and no boat can reach the former without going about ten miles, and the southern point of Scotland. The point of the Mull, on which there is a lighthouse, is a peninsula of about a mile and a quarter in length by a quarter of a mile in breadth. The small island of Wigtown is 2 miles long, which lies about three miles due south, and contains 495 inhabitants. It affords safe and commodious shelter for shipping. Loch Ryan Bay, on the north, extends into the country about eight miles, to Stran-
into Wigton Bay. The river Luce, which falls into Luce Bay after a course of 21 miles from the borders of Ayrshire, is easily crossed on foot, except when floods occur. The other streams of the county are comparatively insignificant. The soil of the Machars and the Rhynies is described as consisting for the most part of a hazily loam, dry, and adapted for the rearing of cattle. There is a tract of rich alluvial land in the eastern part of the county, which extends from the parish of Kirkenmer to Newton-stewart. The Moors are bleak and barren, and in many places covered by peat land pasturage. Out of 286,900 English acres which the area of the county comprises, it is stated in the recent 'Statistical Account' that 101,136 acres, or about 35 per cent., are under cultivation, and 187,324, or about 65 per cent., in pasture. The land is subdivided, in small units under entail, in farms of moderate size, generally for leases of nineteen years. In 1831 there were 820 occupiers of land employing labourers, and 487 occupiers who did not employ labourers. A great impulse has been given to agriculture since 1839, and above 63 square miles. The number of inhabitants is increased. 2539. The course of the river Luce from Stranraer to the royal steamer at the moorings at the entrance of the bay, is about 12 miles, and contains numerous islands, and is freezing during the winter. The river Rhynns, which flows into the river Luce near the town of Wigton, is about 26 miles in length, and is navigable for small vessels. The river Maches or Muck, a stream of six miles in length, flows into the Luce, and is navigable for small boats. The river Luce, in its course, passes through the Kirkcudbrightshire Baronies of Whithorn and Kirkmaldon.**

The town of Whithorn is the county-town, which was made a royal burgh about 1340, and is situated on an eminence about 200 feet above the level of the sea. The harbour is within a quarter of a mile of the town. In his 'Itinerary of the County of Kirkcudbright,' Sir Ralph Verney states that in the middle of the village street a long oblong space has been enclosed and planted with shrubs, evergreens, and forest-trees, and spacious gravel-walks have been laid out, with a bowling-green in the centre. The revenue of the corporation is about £300 per annum. There is a good grammar-school, attended by from 80 to 100 scholars. There is a private bank, and branches of two of the Edinburgh banks. The parish church is an old and mean-looking edifice. In the churchyard there is a monument to the memory of a young man and wife, who were some aged eighteen, and the other sixty-three, who, in 1885, were tied to a stake within the flood-mark and drowned for not conforming to prayer. At the village of Blidenech there is a whisky distillery which concocts 10,000 bushels of malt annually. In 1842 there belonged to Whithorn 20 vessels averaging rather more than 100 tons each, besides several under 50 tons.

The most important harbours are Carty, Wigton, Garlieston, and the Isle of Whithorn in Wigton Bay; Port William on the south side of the town; Portnacrook and Portpatrick, on the Irish Channel. At Carty, which is about a mile and a half below Newton-stewart, vessels of from 35 to 45 tons arrive, and at spring tides those of from 70 to 80 tons can come up. Garlieston harbour was greatly improved by a vote of £3400, raised four years since, and now shelter thirty vessels. The number of vessels belonging to this port in 1833 was 15, of which 4 were each of 100 tons burthen, and the remains averaged 48 tons. Vessels of 100 tons burthen are built here. Portpatrick is the station for the post-office steam-packet to Dungladan, on the opposite coast of Ireland: the distance between the two ports is from 10 to 11 miles. The population has decreased 196 since 1831, and since the introduction of steam-boats the port has been less resorted to. The town is on the Great Southern Green for Ireland. At Stranraer a pier was built about twenty-one years ago, at which thirty large vessels may lie, but they can only come up at high-water. Nearly 40 vessels belong to this port, which average about 48 tons each.

The population of each parish in the county in 1841 was as follows—

The town of Newtonstewart (pop. 1238), in the peaks of Penninghame, and the town of Portpatrick (586) are each a borough of Barony. Wilberforce, (1860) Whithorn, (1831), and Stranraer (430), are boroughs.

**Wilberforce, William,** was born at Hull on the 24th August, 1759. His father, Robert Wilberforce, was a merchant in that town, descended from the ancient Yorkshire family of Wilberforce; his mother was the daughter of Thomas Bird, Esq., of Barton, in Oxfordshire. His constitution was so weak from his infancy, that in after-life he expressed his gratitude, that he was not born in less civilized times, when it would have been thought impossible to rear so delicate a child. He was however as soon as possible placed at school, of good and useful instruction, to enable him, in the early age of seven, a remarkable talent for eloquence. He commenced his education at the grammar-school of Hull, which he attended for two years; but on the death of his father in 1768, he was transferred to the care of his father's brother, Mr. William Wilberforce, Esq., of the middle of the parsonage house, in the town of Hull, where he was educated in a country gentleman's residence. He attended the Grammar School in a mean school near Wimbledon. While at school his uncle, with whom he was an ardent admirer of Whitfield's preaching, first led his youthful mind to contemplate the truths of religion, but at the same time imbued him with her peculiar views. His mother, on hearing that he was in danger of becoming a Methodist, withdrew him from his uncle's care, and placed him at the Pocklington Grammar School, near York, where he stayed five years; and he removed thither, the memory of his uncle's influence upon his future life. He was, however, twenty-six years afterwards, that it had probably been the means of his being connected with political men, and becoming useful in life; and that if he had stayed with his uncle he would have 'gone to the Methodists.'

At Pocklington his serious dispositions were soon disapproved of by a life of ease and pleasure. His talents for society, and his rare skill in singing, made him an acceptable guest with all the neighbouring gentry, and much attention was paid to the editor of the York paper, 'in commendation of the odious traffic in human flesh.'

In October, 1776, he entered St. John's College, Cambridge, at the age of seventeen. Here he was at first introduced to dissolve companions, whose habits were not...
very congenial to his taste, and he soon shook them off and entered into more suitable society. By the death of his grandfather and his uncle he had become possessed of a handsome fortune, which enabled him to indulge in every extenuating hospitality, and discouraged him from exerting himself in his college disputes. In spite of his manadelations to idleness, he became a good classic, and acquitted himself well in his examinations; but the irregular and desultory habits which he acquired were not corrected by new meditations, and he often had occasion to regret that the cultivation of his mind had never been sufficiently attended to.

Before he had quitted Cambridge, Mr. Wilberforce determined to enter upon public life. A dissolution was shortly expected, and he aspired to represent his native town, the established profession not being, in his first year when parliament was dissolved, and, after an active canvass, he was triumphantly returned by the electors of Hull. He now came to London, and entered at once into the first society. He was elected a member of the most fashionable clubs, and became intimate with the leading wits and politicos of the day. He had been acquainted with Pitt at Cambridge, and they now met daily in society, and were inseparable friends. The gaiety of his London life did not distract his attention from public business, and he attended not much in the House of Commons, and, without taking much share in the debates, he formed his own judgment upon every question. He was generally an opponent of Lord North's administration, and particularly adverse to the American war, but occasionally voted with the Whig party. The appointment of Mr. Pitt increased, and the genius which that great man displayed led Mr. Wilberforce to predict his rise: 'He comes out,' he wrote to a friend, 'as his father did, a ready-made seer; and I trust to see in his own works what the first man in the country.' In July, 1782, Pitt took office with the Shelburne ministry, and Mr. Wilberforce was fixed upon to succeed the address on the meeting of parliament in December. From this time a tempting prospect opened to the most ambitious. Pitt bore forth himself and his own wits. As he left Pitt, who almost lived with him at Woburn, and travelled with him on the Continent, was daily becoming more powerful, and Wilberforce's political opinions and position in parliament would have justified him in taking the address himself, he was induced to go into the contest. At length, in November, 1783, Pitt became prime minister, and Wilberforce, being entirely in his confidence, exerted himself strenuously, as an independent member, in support of the new administration. In parliament his speeches attracted more attention than ever before. He had been turned upon him by an event most important to the state of parties and to his own personal advancement. In March, 1784, when the dissolution was approaching, a resolution was brought in by Mr. Grenville, in condemnation of the late coalition ministry, and of which the chief object was to defeat the predominant influence of the great Whig families at the ensuing election. Wilberforce hastened to attend this meeting: he understood the free-trade and religious eloquence and effect. His address was carried; and before he had ceased speaking, a shout arose in the castle-yard, 'We've got him for our county member.' He had secretly cherished a hope of this result, yet, considering the overwhelming power of his opponents, he was not prepared for this. In his enthusiasm he forgot his own personal ambition in the happiness of the cause, and was not therefore surprised at the verdict of the country. As the candidate, he had no difficulty in obtaining the confidence of the body of voters. He was elected by a large majority. Delight and confidence were expressed in every part of the county, and throughout the whole kingdom. The Whigs of the city, the Whigs of the county had all come together; and Mr. Wilberforce had the satisfaction of seeing his friend supported by a vast majority of the House of Commons.

Thus before he had completed his 25th year he had attained a station of the highest distinction, and a career of ambition and power lay open to him; but he was destined to follow an original course, to reject the opportunities of personal advancement which offered themselves, and to devote all his energies, and sacrifice all his means, to the noblest of all religious and philanthropic purposes. The reductions of gaiety and of ambition had never wholly effaced from his mind the religious impressions of his youth, and a tour on the Continent with Isaac Milner, in 1784-5, revived his latent zeal. Henceforward a spirit of earnest piety and devotion took entire possession of his mind, and directed all his actions for the remainder of his life and honourable career. He hastened from abroad to support Pitt's measures of parliamentary reform, and early in the session of 1786 he himself proposed an important plan for purifying county elections, by so adverting to the interests of property, and holding the poll in proper time that the late corruption was the same time. This scheme, so obviously useful, was not carried into effect until enacted by the Reform Bill in 1832. Early in 1787 his religious zeal was made public, by his activity in promoting acceptances of a number of Catholics, and voting for the establishment of a college for the education of priests, and in obtaining a royal proclamation against vice and immorality; but his conduct in the House of Commons had not yet borne evidence of the change in his opinions. He was deeply sensible however of the importance of rendering his public station and influence subservient to the advancement of religion, and only waited for a suitable occasion. His reflections in the autumn of that year were—'Two sessions of parliament gone over, yet nothing done for the interests of religion. My intellectual powers have increased, and I am embarrassed now; such is the state of the government; I have long ceased to be responsible to society; I have failed in my expectations; I cannot give away my principles; I must, as formerly, which is highly criminal, considering the weight to be derived from credit for eloquence in this country.' While under the influence of these feelings, the slave-trade, which had been his interest at school, was again presented to him in his position, he resolved to devote himself to its abolition. Six years before he had interested himself for the West India slaves, and 'had expressed his determination, or at least his hope,' that 'he would redress the wrongs of those wretched and degraded beings;' and now, under the united influence of religion and humanity, he laboured to effect this cherished object. It required no little fortitude to undertake the cause of the negro race; but Mr. Wilberforce was not deterred by the conviction of its hopelessness, and the harassing failures in store for Mr. Wilberforce would have discouraged any man whose exertions were not sustained by the highest principle. He prevailing more upon the humane and religious feelings of the country than upon parliamentary support, he availed himself of the agency of a society of which Granville Sharpe was the president, and Thomas Clarkson the agent. Throughout the struggle, which lasted for twenty years, Mr. Wilberforce was ever unremitting in his exertions. His hopes were deferred. Thwarted at one time by the protracted examination of witnesses, outvoted at others, now in the Commons, now in the Lords, he never flinched from the task of reform, and maintained his cause by many admirable speeches, and by a diligent collection and sifting of evidence. Out of parliament he never lost sight of the great object. In his conversations and his letters he conciliated the support of all parties. Cabinet ministers, opposition members, the clergy of all shades of opinion, and his own familiar friends, were alike solicitous to advance the cause of abolition. No pains were spared to enlighten the public through the press, sometimes by his own pen, and sometimes by the pens of many willing friends. At the same time he was perpetually alive to all political changes at home and abroad, and ready to seize upon any occasion for improving the condition of the negro race by negotiation with foreign powers or by the introduction of new measures. Apart from the opposition which he encountered from the West India interest, the fearful excesses of the French Revolution and the rebellion of the slaves in St. Domingo led many to associate the abolition of the slave-trade with the overthrow of the monarchy. But during the seven years this cause alone retarded the success of his endeavours. Meanwhile, though well fitted, morally, for the labours he had undertaken, it is marvellous how his constitution enabled him to bear against the bodily fatigue which he was forced to endure. The spring of 1788, when his labours were yet to come, his health appeared entirely to fail, from an absolute decay of the digestive organs. The first physician, after a consultation, declared 'he had no more to do in this world; it was now time to lose a formidable life; and although he labours most mercifully, from his illness, we find him excelling on New
day, 1780, `At thirty and a half I am in constitution sixty.'
From his infancy he had suffered much from weak eyes, and his exertions were constantly interrupted or rendered painful by this infirmity. Still rising with new hopes and vigour from every disappointment, he confidently relied upon the ever-increasing success. At length the hour of his triumph was at hand. In January, 1807, he published a book against the slave-trade, at the very moment that question was about to be discussed in the House of Lords. The abolition bill passed the Lords, and its passage through the Commons was one constant triumph to his author. Sir Samuel Romilly concluded an affecting speech in favour of the bill by contrasting the feelings of Napoleon in all his greatness with those of that honoured individual who would this day lay his head upon his pillow and remain as one of the slaves. In the whole house, we are told, burst forth in acclamations of applause, and greeted Mr. Wilberforce with three cheers. He was himself so overcome by the touching allusions of Sir Samuel Romilly, as to be unable to discharge to his own satisfaction the duties of a member for Yorkshire, he was unwilling to retire from parliament, and accepted a seat for the borough of Brent. His activity in his new position appears to have been as unconcealed as before; he endeavoured to use foreign powers to follow the example of England in abolishing the slave-trade. He overlooked no opportunity for furthering this object. The restoration of the Bourbon princes, the Prince of Prussia, Talleyrand, the Duke of Wellington, and Lord Castlereagh, were all in turn solicited, exhorted, and instructed. Even the pope did not escape his solicitation. He endeavoured to secure in condemnation of the slave-trade.

Up to 1822 his public exertions had been confined to the universal extinction of the slave-trade, but his views of the ultimate abolition of slavery itself had not been static, and there was now more desire for the 'more human' and 'more practical' mode of thinking. Though he had no idea of being on the verge of a fall, his health however precluded him from devoting the vast labours to this cause that he had given to the former. He entrusted its management in the House of Commons to Mr. Fowell Buxton, and in 1825 retired from parliament, having completed the task of his life. Nevertheless, he did not give up his object, and in 1834, when the recommendations of the Select Committee on the slave-trade were made, he said, and I believe with truth, that he was more deeply engaged than ever in the abolition of slavery. He died in Cadogan Place, where he had always lived, on Monday, July 29th, 1833, and was buried in Westminster Abbey, with all the honours due to a statesman and a statesman of the highest eminence. His remains were placed in the vault of the Church of St. Bride, whose clergy and benefactors he were benefactors.

WILBORD, or WILBROD, SAINT, commonly characterised as 'The Apostle of the Frisians,' was bishop of the Saxon kingdom of Northumbria, where he was born about the year 657. His father's name was Wiglaf. He was educated at Ripon, and was appointed a disciple of St. Cuthbert, and subsequently consecrated bishop of the Frisians, and was a bitter opponent of the Anglo-Irish Church. The latter of these had been established in Friesland, and had there preached Christianity two years in vain. Wilbord remained for thirteen years in Ireland, and then resolved to attempt the conversion of the Frisians himself. His arrival at Tournai was without a contest, and he was received into the church by the bishop, with his attendants or disciples to the number of twelve, the Frisian bishop Perpin, and the two prelates were greeted with a warm welcome. The latter resolved to add to the influence of the monarch that of the pope, and with this end in view he visited Rome in 692. Three years afterwards he gave a second visit to the head of the church, and, receiving the
WIL, No. 1727.

WIL. HENRY, known as the learned tailor, or the Arabian tailor, was a native of the city of Norwich, where he was born about the year 1584, and where he received the usual elementary education in Greek and Latin at the grammar-school; on being taken from which, however, he was bound apprentice to a tailor, with whom he is said to have served seven years in that capacity, and then to have worked seven more as a journeyman. Long before the fourteen years his Greek and Latin had probably been nearly altogether forgotten; but he was now seized with an illness, which at last obliged him to give up working, and in this state he took to reading as an occupation for his idle hours. It is either by accident or taste led to, were some old works of controversial divinity: and the quotations from the Scriptures in the original Hebrew, with which they happened to be interspersed, are said to have first excited him to an attempt to make master of that language. In prosecuting this object he by degrees recovered his Latin, thus enabling himself after some time to exchange his English Hebrew lexicon and grammar for school works of that kind in Latin; and, what was of still more importance, in the course of his studies he also recovered his health, and was enabled to resume his trade. But he did not upon this lay aside his books: he worked part of the day, and devoted the rest, and often an entire portion of the night, to study, so that at last he made himself acquainted with others of the Oriental languages as well as the Hebrew. In March, 1714, he is mentioned as having within the preceding seven years mastered Latin, Greek, Hebrew, Chaldaic, Syriac, Arabic, and Persian.

WILDENS, JOHAN, a celebrated Flemish landscape painter, born at Antwerp. He was the contemporary of 

Vol. XXVII—3 C
Rubens, to many of whose pictures he painted landscape backgrounds, which he knew how to harmonise with the style and colouring of Rubens better than any other landscape painter. Rubens is said to have preferred the works of Wildens to those of Van Uden, whom he employed in the same way. Wildens painted large and small pictures, in some of which there are some good figures painted by himself; but in his best works the figure is placed in the background of the landscape. He painted twelve charming and characteristic pictures of the twelve months, which have been engraved. He died in 1644: the year of his birth is not known; 1594 and 1600 are both given by different writers. (Cf. Encyclopaedia, Vol. xi.)

WILFORD, FRANCIS (Lieu.-Col.), known as an Oriental scholar by numerous contributions to the 'Asiatic Researches,' went out to India, in 1791, as lieutenant of some troops which were sent from Hanover, his native country, to underwrite the East India Company's interests. In 1801, he was given a pension of £100 p. a., and the post of second assistant in the Department of Asia in the India Office. He proceeded to India in 1796, and after a residence of more than a year in Madras, where he was stationed at Rassaputilla, where he devoted some of the time which was not occupied by his professional duties to the elucidation of Buddhist antiquities by means of whatever notices were available to him, and by the cooperation of his authors: he found however great difficulties from the total ignorance of the Oriental languages; and in his first essay, which was published in the 'Asiatic Researches' (1797), he complained of not writing any time to the Oriental languages. Two years afterwards he was stationed at Benares, the centre of Hindu learning, where he engaged a Pandit to instruct him in the sacred dialect, and more especially to point out to him those passages from the Vedas and Puranas which were relative to geography. The result of his investigation was an essay on 'Egypt and the Nile, from the ancient books of the Hindus' (1792). It is needless to say that the Pandit had forged authorities to suit the fancies of his unsuspecting employer; yet so skillfully were the forgeries put forth, that the essay was accepted by the Pandit himself, and the imposture was thereupon imputed by both. Wilford himself describes the imposition as carried on, in the following manner:

'I directed my Pandit to make extracts from all the Puranas and other books relating to my inquiries, and to arrange and copy them; and gave him a pension of seven rupees for his assistance and writers, and I requested him to procure another Pandit to assist me in my studies; and I obtained, for his further encouragement, a place for him in the college at Benares. At the same time I amused myself with walking to all the regions or islands, within the elevated and mountainous country, which was under his charge. And the Brahman immediately substituted the word Egypt for the name of any other country mentioned in the Puranas. We have thought it worth while giving the above extract, for it now renders it entirely impossible to give a determination as to the countries, which we shall mention, with a warning to our readers not to trust even those which he wrote after discovering the imposture in 1804. This circumstance greatly disturbed his peace of mind, and brought on paroxysms, which threatened the most serious consequences to his then infant state of health. He was an original member of the Asiatic Society, and associated with the learned men of the Institut de France (Academie des Inscriptions et Belles Lettres), and was elected a fellow of the 4th Society. Everywhere is a list of his essays, which show great zeal for his subject, but an utter want of sound judgment. They are all inserted in the 'Asiatic Researches':—1. 'Remarks on the Town of Sagar,' i. p. 309 (1797); 2. 'On Egypt and the Nile,' ii. p. 252 (1798); 3. ' Dissertation on the Semiramis,' iv. 303; 4. 'An Account of some ancient Inscriptions,' v. 135; 5. 'On the Chronology of the Hindus,' v. 247 (1797); 6. 'Remarks on the names of the Cabiri,' v. 267; 7. 'On Mount Caucassus,' vi. 435 (1799); 8. 'Of the Navigation of the Red Sea,' xi. 222 (1805); 9. 'Chronology of the Kings of Media,' ix. 62; 10. 'Zira of Vikramaditya and Saliwhansa,' ix. 117; 11. 'On the Antient Geography of India,' xiv. 363 (1809).

WILFRED, SAINT, a Saxon bishop, one of the principal instruments by which the papal authority was extended to Britain. He was descended of a noble family of Berwick, where he is said to have been born in the year 634. He was taught the use of arms and the other accomplishments of a Saxon noble. At the age of thirteen he lost his mother, and became subject to the authority of an unknown step-mother, from which he was relieved by being received into Queen Eanfleda's household. While only in his fourteenth year he was directed by the queen to be an attendant on an aged Saxon noble named Cista, who had resolved to spend his last days as a layman and patron of a small monastery in Lindisfarne. It is said that Wilfred here devoted himself to theological reading, in the course of which he discovered the difference between the practice of the Scotch church and that of the rest of the Christian world as to the observance of the Paschal week, and conceived the design of visiting Rome, that he might obtain a satisfactory solution of the difficulty. In the year 683, when nineteen years old, he proceeded on this journey, accompanied by Benedict Bishop, who afterwards quitted a celibate life, and travelled about the kingdom. He was received into the church of Birnie and Kest. At Rome, where he remained for several months, he received special instruction on the subject as to which he had made inquiries, and on theological matters of more serious importance in the concourses of the Church. He was then called back to the Saxons. The ceremony was performed in time to give him a voice in the celebrated conference of Synod of Whitby, where the Easter question and that of the tonsure were solemnly discussed. The Scot-Irish clergy having received the benefit of the decision of the Council of Council, and authority, Wilfred naturally obtained a high influence in the Synod, in the year 664. He was consecrated bishop of Lindisfarne, and given the jurisdiction of the See of York, as of Wilfrid, bishop of Lindsey, the king of Northumbria, whose dominions were under the spiritual jurisdiction of the Scotch bishops of Lindisfarne, and whom he desired that his clergy should conform to the practice of the rest of the Church. He held the authority. The conference was held at the monastery of Whitby, at the commencement of the year 664. His practice was vindicated by Colman, bishop of Lindsey, on the example of St. Columba; but Wilfred addressed the higher clergy to the Church of St. Luke's, as a matter of his own concern, on the ground that if he refused to obey the decision of St. Peter, he might find on his arrival at the gate of Heaven that they were looked against him. The jurisdiction of the Scotch bishops within Northumbria was given to the Scotch clergy from the circumstance of the sea of York being kept vacant. The king determined to fill the sea, and the choice naturally fell on Wilfred. He saw difficulties in the way of being canonically consecrated in Britain, and proceeded to France, the ceremony was performed on the 18th of March, 1222. The church was much pleased by the same arrangement, and ordained him priest, and who had become bishop of Paris. The ship in which he returned was driven by a storm on the coast of Sussex, where he and his followers narrowly escaped being plundered and murdered by the sea of York, and the inhabitants. In the meantime the influence of the Scot-Irish and British party in the church had got one of their own number, Ceadael, placed in the chair of York. Three years elapsed before Wilfred could get his claim confirmed in the synod of Whitby, when he came in the year 682; but his elevation to the archiepiscopal see of Canterbury, decided the contest in favour of the Roman party in 688. Wilfred, in possession of his bishopric, soon showed the ambition and priestly pride of his character by enforcing the attendance at the church and services; and with a pomp and state. He exhibited within the narrow limits which Christianity then filled in England the same features of character which Hildebrand and Becket displayed on a
larger scale. He carried on a bold contest for superiority on the side of the ecclesiastical against the kingly power, both of them but imperfectly developed, and depending for their extent very much on the personal character of the individuals who might wield them. He appears not to have been luxurious or sensual in his own personal habits; but he lived magnificently, kept a great table, and was surrounded by a body of attendants, which vied in number and splendour with the apartments of the warden of a Bucking- ham palace. His devotion to literature and the society of eminent men did not secure his youth from vicious excesses. He was notorious for his dissipation and extravagance, and at an early age was embroiled in fortunes and tainted in character. In 1740 he married Miss Chatham. His devotion to literature and the society of eminent men did not secure his youth from vicious excesses. They continued to live together for some time, and a daughter was born of their marriage; but at length his excesses and mutual disagreement led to a separation of the couple. This was followed by a series of wild orgies, during which he was seen about town with a young woman, in which his character was exposed to much obloquy. His vices however were not destined to ruin him. Neither his character nor his talents would have guided him to political eminence; but the imprisonment and illegal measures of his opponents made him the idol of the people.

The first appearance of Wilkes in public was in April, 1754, when he addressed the electors of Berwick-upon-Tweed with a view of becoming their representative in parliament. He did not however succeed in obtaining a seat in the House of Commons until 1757, when he was returned for the borough of Aylesbury, for which place he was re-elected in the next parliament, in 1761. In March, 1765, he published the first number of the North Briton, a newspaper, the 'North Briton,' which he undertook in opposition to 'The Britton,' a paper written in defence of Lord Bute's administration. The unpopularity of Lord Bute was already manifest, and the paper increased it to an alarming extent, by stirring appeals to the passions and to national prejudices. The minister quailed before the clamour with which he was universally assailed, and withdrew from public affairs; but his known influence over the king, and the political connection of his chief ministers under Mr. George Grenville, his successor, led to the belief that he still enjoyed a secret control over the national councils. Wilkes, with the assistance, it is said, of Charles Churchill and Lord Temple, continued his attacks upon the government with unceasing energy. The government were watching an opportunity of punishing their mischievous opponent, and at length struck a blow which recoiled upon themselves. In No. 45 of his paper he charged the king with having uttered a false and libellous falsehood in his speech from the throne, and sentenced him to be 'tainted of the North Briton,' an act of sedition and treason. The court of law, however, overruled the decision of the House of Commons, and the 'North Briton' was entered by three king's messengers, his papers were searched, and he himself was seized and committed to the Tower. In a few days he was brought, by aboeus corpus, before the Court of Common Pleas, and discharged out of custody on account of his privilege as a member of the House of Commons. An information however was immediately exhibited against him by the attorney-general, to which he declined to appear. He was, at the same time, dismissed from his command in the militia, and his friend, Lord Temple, was deprived of his office of lord-lieutenant of Buckinghamshire.

On the meeting of parliament in November (1768), the House of Commons were acquainted, by a message from the king, with the proceedings of the court, and the sentence on the paper. The number of the 'North Briton' was laid before them. They immediately resolved that the paper was 'false, scandalous, and seditious libel,' and ordered it to be burnt. The hands of the printers of London proceeded to execute this sentence at the Royal Exchange, they were insulted by the mob, and a riot ensued, the first of many tumults in the cause of Mr. Wilkes. That which had been intended as a disgrace and punishment to Wilkes was thus turned into a raucous scene over the ministers and the parliament. The people had regarded his imprisonment by a general warrant as illegal and oppressive, and his paper, though adjudged libellous as
higher quarters, was read by them with enthusiasm, and its author greeted everywhere with the loudest applause. On his return to the Tower, Weymouth had brought charges of the disorder against the under-secretary of state for the seizure of his papers; and the cause now coming on for trial, he obtained a verdict in his favour, with 1000l. damages. On this occasion Chief Justice Pratt, afterwards Lord Camden, declared the decision to be "unconstitutional, illegal, and absolutely void." [Warrant]

Meanwhile Wilkes had been called upon by the House of Commons to answer the charge of being the author of an open and large unconstitutional, obscene plate, the Thor, afterwards formed and printing and published with an essay on Woman." The latter was an obscene poem of which he had printed only 12 copies, and one of them had been surreptitiously obtained through a printer who had been employed at his private press. By recovering this copy and the use of it he hoped to increase the enthusiasm of the people in his favour; but the means to which they had resorted in obtaining possession of the book, increased the indignation against the government, and the sympathy for the victim of ministerial persecution.

Wilkes remained abroad, and not appearing to receive the judgment of the court, he was outlawed. He travelled on the continent for some years, but did not lose sight of his interests at home. He solicited pardon for the past, and application for a pension or a pension on the ruins, and it is said that he obtained a pension of 1900l. a year from the Rockingham administration, paid out of their own salaries, viz., from the first lord of the treasury 300l., and from the lord of the treasury 60l. each, from the lords of trade 40l. each, &c. (Letters, &c., in the case of J. Wilkes, late Member for Aylesbury," by which he hoped to keep alive the public interest in his favour. In 1769 he returned to England, and in March of that year offered himself as a candidate for the representation of the City of London. He succeeded in polling 1247 votes, but in spite of the violent attachment of the populace, he failed in obtaining a majority. He then declared himself candidate for the county of Middlesex, and on the 28th was returned by a large majority. Serious riots occurred at both these elections, and the court party declared that the City, and even the king's palace, were in danger. Although an outlawry was hanging over his head, Wilkes went privately to prison at the time, and to appear on the hustings, and harangue immense mobs in London, Westminster, and Brentford. After his election he surrendered himself before the Court of King's Bench, but the court refused to commit him upon his outlawry, as moved by the attorney-general, and he was accordingly discharged. He was arrested immediately afterwards on a writ of *copias ululatuum*. A tumult arose, and as the officers were conveying him to the King's Bench prison, he was rescued by the mob. Not thinking it prudent to force his way to the House, he went privately to prison after the dispersion of the mob. He was still under confinement at the meeting of parliament on the 10th of May, and a mob assembled before his prison to demand his liberty. A riot ensued—the military were ordered to fire, and killed and wounded several of the rioters. The death of one person was brought in murder by the coroner's jury, and the magistrate who had given the order to fire was tried for murder and acquitted. The violence which had been resorted to by the popular party as the massacre in St. George's Fields, and the subject of angry complaints against the government. Mr. Wilkes's outlawry was afterwards reversed by Lord Mansfield, but judgment was pronounced upon him for his two libels, and he was sentenced to two fines of 500l. each, and to imprisonment for the two terms of 10 and 12 months. Not contented with his imprisonment, the ministers devised fresh means of persecution against Mr. Wilkes, which, like their previous measures, increased his popularity and diminished their own. He had continued to obtain a copy of the letter addressed by Lord Weymouth to the friends of the under-secretary, to Lambeth, before the riot in St. George's Fields; in which that nobleman recommended the early and effectual employment of the military to suppress disturbances. The letter was published by Mr. Wilkes, and he charged the secretary of state with having 'planned and determined upon the horrid massacre in St. George's Fields' three weeks before its execution. Lord Weymouth complained of this publication in the House of Lords as a breach of privilege, and the case was decided by Lords to the Commons, and a conference held upon the subject. When Mr. Wilkes was brought to the bar to be heard upon a petition which he had presented, he avowed himself the publisher of Lord Weymouth's letter, and the author of the prefatory remarks; upon which it was resolved that his remarks were a scandalous and seditious libel, and, for the second time, expelled him.

A new writ was issued for Middlesex, and Mr. Wilkes was re-elected without opposition and without expense. The House discovered that the writ was void by reason of the expulsion, and issued another writ. Mr. Wilkes was again chosen without a contest, when the House declared him incapable of being elected into that parliament. Nevertheless, when the writ was again returned, the House decided, when Mr. Dingley, his opponent, could not even obtain a nomination, and Wilkes was returned a third time without opposition. This election was likewise declared to be void, and this time a new expeditor was returned to the government persuaded to take its seat in parliament, and to oppose Mr. Wilkes in the approaching election. Mr. Wilkes was returned by an overwhelming majority, and his opponent mustered less than 300 votes, yet the House of Commons declared that Mr. Wilkes had been incapable of being elected, and Mr. Luttrell, being next on the poll, and qualified to sit in parliament, was duly elected as member for the county. This violation of the rights of election was resented not only by the fireeholders of Middlesex, but by the whole country, though still immersed in the King's Bench prison, was receiving substantial marks of public favour. Subscriptions were opened for the payment of his fines and personal debts, and upwards of 20000l. were raised for that purpose. The King, in the meantime, was also heaped upon him plate, jewels, wine, furniture, and embroidered purses of gold. His portrait was in universal request, and was reproduced in every form of art, from the marble bust to the village sign-board.

Another legal triumph soon followed. On the removal of his outlawry, Mr. Wilkes had proceeded with an action against Lord Halifax for false imprisonment and the seizure of his papers. In November, 1769, the cause was tried in the Common Pleas, where he obtained a verdict, with 1700l. damages for the wrong done to him in triumphing over the House of Commons. The House of Commons, though still immured in the King's Bench prison, was receiving substantial marks of public favour. His subscriptions were opened for the payment of his fines and personal debts, and upwards of 20000l. were raised for that purpose. The King, in the meantime, was also heaped upon him plate, jewels, wine, furniture, and embroidered purses of gold. His portrait was in universal request, and was reproduced in every form of art, from the marble bust to the village sign-board.
solutions of the House of Commons in regard to the Middlesex elections; but at length, on the dissolution of Lord North's administration in 1782, he accomplished his object. On the 3rd May, the House voted that the resolution of the February, 1782, by which he had been declared incapable of re-election, should be expunged from their journals, 'it being subversive of the rights of the whole body of the electors of the kingdom.' All the other resolutions and orders of the House concerning the Middlesex election were also to be expunged. In 1784 he was elected for the last time by the county of Middlesex; he did not offer himself again at the dissolution in 1790, but retired into private life.

In attempting to shun the world, he was forgotten, and died December 27, 1797, at the age of 70. He was buried in Grosvener Chapel, South Andley Street, where he directed a tablet to be placed, with this inscription:—'The Remains of John Wilkes, a Friend to Liberty, born at London, Oct. 17, 1727, One who did with his life, his blood, and his fame, render the name of Freedom glorious in the history of the world.'
WIL

He began his career as a painter's assistant, but quickly rose to fame. His works were highly sought after, and he was awarded numerous medals and prizes. Wilkie was known for his realistic depictions of everyday life, particularly in Scotland. He was also celebrated for his portraits, which were highly regarded for their attention to detail and emotional depth. Wilkie's paintings were widely exhibited in Scotland and England, and his work has been influential in the development of Scottish art. He was a key figure in the Scottish School of painting, and his works continue to be celebrated for their emotional resonance and technical skill.
mision, he makes the following excellent observation:—

"From Giotto to Michael Angelo expression and sentiment
seem the first thing thought of, whilst those who followed
seem to have allowed technicalities to get the better of
them, until, simplicity giving way to intractacy, they seemed
to be hurried on by the artist and the connoisseur then
for the untutored appreciator."

In Italy Wilkie remained eight months. He then visited
Munich, Dresden, Tsplitz, Carlsbad, Prague, and Vienna,
and returned for another season to Italy. At Viesens he
began a portrait of a gentleman, thence to Florence
where he stayed two months. At Rome, on his second visit, a public dinner
was given to him by the Scotch artists and amateurs, at which the Duke of Hamilton
presided. During his second visit to Italy his health began to revive, and he
produced from a series of works, exhibited through the south of France, entered Milan,
and travelled to Madrid. In Madrid he painted a picture of a Spanish Council of War,
and two other Spanish sitters, one of which was the Defense of Saragossa,
in which he inserted the portrait of General Pol, the
defender of the place.

In the summer he left Spain, and
reached Paris in June, 1828, and returned to England in the
same month, after an absence of three years. In the exhibition of 1829 he had eight pictures of
Italian and three Spanish, and a portrait of Sir John Kempe of Kelkie. The three
Spanish and two of the Italian were purchased by
George IV. In the same year he painted a portrait of the
king in a Scotch dress. Some of these pictures were much admired by
the Queen, and John Knox, whose
principal characteristics are effect of colour and light and
shade, which, with breadth and facility, he appears to have now
considered the proper objects of high art, and an
advance beyond the truth, simplicity, and character of his
rivals. The knighthood of the order of the
class who allowed themselves to be engaged by
artists, and, to use his own words—"seem to have painted
more for the artist and the connoisseur than for the un
informed appreciations of ordinary men." Of this new style
in portraits he was one of the first English artists to see,
from the study of the old masters, adopted a bolder and,
I think, more effective style, and one result is rapidity."

In other letters he speaks of his impression of Rembrandt, Cor
nerenge, and Velasquez. After the death of Sir Thomas
Lawrence, inserted, which was approved in his place
painter in ordinary to his Majesty: he was also a candidate
for the office of president of the Academy; but there was
only one vote in his favour, Sir M. A. Shee being the suc
cessful candidate.

In the year 1833 he exhibited his full-length portrait of
George IV. in a Highland dress, and the king's entrance
into Holyrood. In 1831 his only works in the exhibition
were portraits of Lady Lynham and Lord Melville.
In 1834 he exhibited a series of pictures, magnificent, like
preaching the Reformation in St. Andrews, painted for
Sir R. Peel for 1200 guineas; and a full-length of William IV.
The John Knox is a work of a very high class, though
a less glowing colour and a more careful execution are
wanting to constitute it a work of first-rate excellence:
It has been engraved in a very masterly manner by Mr. Doe.
In 1833 he exhibited a portrait of the Duke of Buinen in a
Highland dress. In 1834 he exhibited six pictures
of which four were portraits, among them the Duke of Wellington,
his picture, the great attraction of which was his fine picture of
Christopher Columbus submitting the chart of his Voyage
for the discovery of the New World to the Spanish authori
this is a picture of much fine character, with
mechanical effect. Wilkie's works were the
others were portraits. His next principal works were,
Peep-o'Day Boy, painted after a visit to Ireland; and
Napoleon and the Pope in conference at Fontainebleau,
exhibited at the Royal Academy, in 1830; the Queen's First Council and a
portrait of O'Connell. In 1839, his large picture of
Sir David Baird discovering the body of Sultan Tippoo Saib
after staining Birkenapstaum, painted for Lady Baird for
1800 guineas, and generally considered his greatest histori
history. Mr. Burnet is now engraving it for Mr. Moon,
the publisher of so many prints after Wilkie. In 1840
Wilkie exhibited eight pieces: the most striking was that of
Benvenuto Cellini presenting for the approval of Pope Paul
III. a silver Vase of his own workmanship. His portrait
of Queen Victoria, exhibited at the same time, was generally
considered a complete failure. In the autumn of 1840 Sir
David set out on a journey with a friend, Mr. B.; and upon
his tour to the East: various rumours were circulated as
the cause of this journey, but probably none quite correct.
He went by Holland and the Rhine to the south of Ger
many, Prague, Vienna, Constantinople, and

The description of the first sitting:—12th December.
Drove with Mr. Pisanon to the winter-palace of the Sultan;
vans were put in the carriage, in which,
the pictures, after waiting some time, were conducted, through
a beautiful garden, to the palace, changed shoes, and were
ushered up a staircase to a most splendid and comfortable
room; here I put out the colours, easel, and placed chairs;
and leaving the windows all but one darkened, stated that
all was right. After a time his Imperial Majesty the Sultan
arrived: his style was simple and gentlemanly, and his recep
for me very gracious. On taking his seat, his Majesty
addressed me a few words, which Mr. Pisanon interpreted,
to be that he was the most distinguished artist from England, to sit for his portrait,
considering that doing so might show his consideration for
the Queen of Great Brittain, who was so powerful an ally of the
Empire. I bowed gracefully to his Majesty to be seated.
I began the head. I said and looked at it in different times:
I understood he remarked I was making it too
little; then asked if it was to be standing. I assured him
no, but sitting on the throne as Sultan, receiving people
and judging, etc., etc. He said, "I shall
form with the epaulets be seen?" But I urged that for
this picture the cloak of the Sultan would be better,
and that the hands and sword would be seen: this seemed to
please him, and I went on; and I think he thought it like
and pleasing. The Sultan viewed it with admiration,
and said I had some drawings to show his Majesty.
He looked them over, as I thought, with much attention and
slowly—appeared pleased with that of Admiral Walker.
He asked when I should come again; I said, whenever his
Majesty would command. He said Monday, at the same
time. "I sat about an hour and a half; got the face
nearly painted; returned, both Mr. Pisanon and I, highly
satisfied: left the panel and colours in the room."

In January his picture of Sultan IV.
Constantinople by steam for Smyrna, where they arrived on
the 14th. They left Smyrna on the 1st of February, arrived
at Rhodes on the 2nd, and at Beyrut on the 9th. At this
time, says Wilkie, the weather was remarkably fine, mild,
and delicious: the days were long, and there was
no instance of any dark cloud or a maelstrom.
At Jaffa on the 23rd and at Jerusalem on the 27th of the
same month, after a journey from London of six months and
twelve days. Wilkie describes as follows the impression
made upon him by the first sight of Jerusalem—after
ascending an eminence on the road from Jaffa, he says,
"We saw,—and, oh, what a sight!—the splendid walled
city of Jerusalem. This struck me as unlike all other
cities: it recalled the imaginations of Nicolas Poussin—a
city not for everday, not for the present, but for all
time. We in the hot land we visited the Dead Sea,
and tested its level by the barometer of Mr. J. Harvey, who
had lent it to Sir David for that purpose. At Beyrut the
mercury varied from 80-186 to 20-08, the thermometer at
the Mediterranean 70 and 60 on a level. But in passing
with the Dead Sea it rose to 31-372, the thermometer at
68; showing that the level of the latter is much below than
that of the Mediterranean.

On the 17th of April they left Jerusalem for Jaffa
and then took the road to Damascus in Egypt, whence they
started on the 22nd for Alexandria, where they put up at
Wagborn's splendid hotel. At Alexandria Wilkie complained of
illness; he had felt slightly unwell for the last
three months. He commenced a portrait of Mehemet Ali
at Alexandria, who wished the picture, and painted it in
very patiently two hours and a half the first sitting.
On the 21st of May he embarked on board the Oriental for
Egypt; on the 26th it arrived off Malta; on the 1st of June they arrived off Egypt, and at half-past eight in
the evening of the same day his body was committed to the
deep, in lat. 36° 20' and long. 6° 42': the burial service
was performed by the Rev. James Vaughan, rector of Wilt,
and the promenade appears to have been hastened by
industriously indulging in fruit and iced lemonade
at Malta. On the 28th of August, 1841, a meeting of
the friends of Sir David Wilkie took place at the
Thatched House Tavern, St. James's Street, at which Sir
Robert Peel presided. The result of the meeting was,
that a subscription was commenced for the purpose of erecting
a suitable monument to the painter: 2000l. have been col-
clected, and a statue of Sir David Wilkie, to be executed by
Mr. Joseph, is to be placed in the inner hall of the National
School.

Wilkie was tall and of sandy complexion, with sharp
eyes, was polite and mild in his manners, was a staunch
member of every club in town, and, though he was not
able to do so, in the same way there are a series of remarks
upon painting by Wilkie, which contain many sound views,
and are in parts very well written.

Wilkie's works are well known by the excellent engravings
in Raeburn, Burnet, Cousin, Doo, and C. Fox. A
set of coloured prints in imitation of Sir David's Oriental
sketches has been lately published by Graves and Warmes-
yond, London. It might be added that Wilkie's Life is an
appendix containing a list of all his works, with the pro-
prietary names, and the prices received for them by the
painter. At the sale of his effects, which realised several
thousand pounds, there were many unfinished works, some
of which were brought at very high prices: an unfinished
picture of the School sold for 700l.

(Allan Cunningham, The Life of Sir David Wilkie, with
his Journals, Tours, and Critical Remarks on Works of Art,
and a Selection from His Correspondence, London, 1841.
for the Edinburgh Review.

WILKINS, JOHN, Bishop of Chester in the reign of
Charles II., was, according to Anthony à Wood, 'a person
endowed with rare gifts,' a noted theologian and preacher,
a curious spirit in several matters, an excellent mathema-
tician and experimental artist as well seen in mechan-
isms and new philosophy (of which he was a great pro-
motor) as any of his time.' He was the son of Walter
Wilkins, a goldsmith and citizen of Oxford, but was born at
Oxford. He was educated at the University of Oxford,
and was nonconformist of some note, and author of several theo-
logical works, from one of which, an Exposition of the Ten
Commandments, he is styled 'the Decalogist' at Fawse-
ye, near Daventry in Northamptonshire, in the year 1614.
While engaged in the work, he became dangerously in-
jured, for he was in the drawing-school, at the age of
thirteen, that he claimed a student at New Inn Hall,
where he shortly removed to Magdalen Hall, where for
a short time he was under the tuition of John Tombes,
the celebrated Anabaptist and opponent of Baxter. Tombes
left the University while Willis was an undergraduate,
and did not proceed to his first degree at the usual
time; but he took the degree of B.A. October 20, 1631,
and that of M.A. June 11, 1634. Having then arrived at
the age of twenty-one, he took orders, and became success-
ively chaplain to William, Lord Say; George, Lord
Berkeley, and Charles, Count-palatine of the Rhine, with
whom he resided for a considerable time while he was
in England. The skill of Wilkins in the mathematics,
to which that prince was much attached, is said to have been
his chief recommendation for the last-mentioned appoint-
ment, and for which he was in great demand in different
countries. During this time he wrote several
small treatises on mechanical philosophy. His early edu-
cation had given him a strong bias towards puritanical
principles, and he was strong in the Puritanical phi-
wisely, and in his political views he was taken up
an anti-puritan, and was rejected from the party,
which he entered before the Restoration, on the
basis of his views on the subject of//-m:, from
which he was more than once in prison. After the
Restoration, he was appointed chaplain to
William, Duke of Gloucester, and
under the protection of the Earl of
Northumberland, he went to Paris,
where he entered the University
and was admitted a student in the
College of France. Here he became
the pupil of the great French
philosopher, Descartes, and was
particularly interested in his
system of philosophy, which he
adopted with great zeal. He
also became a close friend of the
great French mathematician,
Fermat, and was deeply interested
in his work on analytic geometry.
Wilkins returned to England in
1653, and was appointed chaplain
to William, Duke of Gloucester,
and later to the Prince of Wales.
He was also employed in the
preparation of the works of
Descartes, and was one of the
commissioners appointed to
translate the works of
Descartes into English.

Wilkins's opinions on ecclesiastical subjects
led to the formation of the Royal Society. According to
Bishop Sprat and Dr. Wallis, indeed, he was the principal
mover in the foundation of that society. According to
him, the main purpose of the Royal Society was to
advocate and promote the study of natural philosophy,
and to prevent the introduction of foreign ideas into
Britain. He was also one of the founders of the
Academy of Mathematics, which was established in
London in 1662.

Wilkins was a man of great learning, and
his works are still valued for their
accuracy and scholarship. He was a
prominent figure in the early
history of science in England,
and his influence was felt in the
development of the Royal Society
and the Academy of Mathematics.
his day, they contain much that is chimerical and absurd. The principal are the following:—1. "Discovery of a New World; or a discourse tending to prove that it is probable that there may be another habitable world in the Moon; with a discourse concerning the possibility of a passage thither."

2. "Two Discourses concerning the possibility of a passage thither."

3. "A discourse called the other world which he supposes to exist in the moon, and if there be inhabitants there, to have commerce with them, is perhaps the only one that could be seriously open to the consideration of musical artists, as it appears to be a deed of proving that the construction of a flying-machine of sufficient capacity for such a voyage by is by no means the chimerical absurdity which most, even in the present day, would consider it."

4. "Mathematical Magic, or the Wonders that may be performed by Mechanical Geometrical," a singular work, the object of which is to make them all, and to determine the proper numbers for any purpose."

5. "Alphabetical Dictionary, wherein all English words, according to their various significations, are either referred to their places in the Philosophical Tables (in the Essay) or explained by such words as are in those tables."

6. "An Essay towards a Real Character and a Philosophical Language," a work founded upon or suggested by a treatise published a few years previously by George Dalrion."

There are several reprints of these works. Wilkins left his papers to the care of his friend Tillotson, allowing him to use his own discretion as to publishing any of them; and in 1675 appeared a treatise "On the Principles and Duties of Natural Religion," which he had left in an unfinished state. In 1682 Tillotson published a volume containing fifteen of Wilkins's sermons, and some others were published separately during his life and also after his decease.

(From "Woods Athenae Oxonienses by Bliss; Burnet's History of the Art Time: Biographical Britannica.")

WILKINS, SIR CHARLES, Knight and K.C.H., was born in the year 1749, at Frome in Somersetshire. His father, Walter, derived his descent from an ancestor of the earls of Albemarle. His first volume was "The English Vagabond," written in 1684, and was reprinted in 1701.

In 1708 he was appointed to the post of "The False Queen," written in 1692, and was reprinted in 1701.

Wilkins left his papers to the care of his friend Tillotson, allowing him to use his own discretion as to publishing any of them; and in 1675 appeared a treatise "On the Principles and Duties of Natural Religion," which he had left in an unfinished state. In 1682 Tillotson published a volume containing fifteen of Wilkins's sermons, and some others were published separately during his life and also after his decease.

Arabic and Persian, as well as of some of the spoken languages of India. He effected this at a time when such studies were generally neglected, and when no part of them had yet been made compulsory. In the year 1778 he aided the efforts of the Governor-general Hastings for improving the education of the masses, by translating the Bengalee grammar of Haldhed, who, in his preface, informs us that having failed to obtain types of the Bengalee character from the ablest artists in London, he had had recourse to Mr. Wilkins, whose success was complete. This book, which contained an original and unique work, was published in 1778. It may be said to have a singular charge himself with the various occupations of modern linguists, as a collector, translator, and printer. Mr. Hastings, in a letter to the chairman of the Court of Directors, remarks, that 'to the ingenuity of Mr. Wilkins, unsaid by models for imitation or by artificers for his direction, the government was indebted for its printing-office, and for the many official purposes to which it had been applied.'

Life of Sir William Jones, attests, that 'the art of printing had been introduced into Bengal by the untaught skill of Francis Wilkins, and to this we shall always bear an intrinsic value from its containing as extraordinary an instance of mechanical abilities as has perhaps ever appeared. In a country so remote from all connection with civilized nations, in a people so ingenuous, and of such feeble minds.'

In the same manner Mr. Wilkins formed a set of Persian characters, which the Bengalee, continued to be employed for the service of the Company. As the inefficiency in the native languages advanced, he became more convinced of the importance of endeavouring to make himself master of that parent dialect which he found diffused through the whole of the modern literature, and science of India. He continued therefore during the remainder of his residence in that country to follow this hitherto untrodden path of science, and thus has justly obtained the title of 'the Father of Sanscrit Literature.'

It is unfortunate that Mr. Hastings and William Jones, and of enjoying the intimate friendship of those distinguished men, who took the most lively interest in his literary pursuits, and whose approbation stimulated his exertions; nor can it be doubted that his knowledge of the Oriental languages, and the salutary influence which his Sanscrit learning gave him over everything connected with the Brahmins, were often eminently useful in the civil and judicial government of India. A MS. letter of Sir William Jones addressed to Mr. Wilkins, which are in the possession of his family, are numerous instances of Sir William's references to him in aid of his own studies in Sanscrit, as well as relating to questions connected with his judicial office. In one of these letters he says that you are the least understood Sanscrit.' In another, it is of the utmost importance that the stream of Hindu law should be pure, for we are entirely at the mercy of the Hindu lawyers through our ignorance of Sanscrit.'

In the year 1784 Mr. Wilkins was instrumental, in union with the same accomplished scholar, in establishing the Literary Society of Calcutta, whose publications, called 'The Asiatic Researches,' were regarded with the greatest interest by the learned of Europe. A separate work however of his own operated perhaps still more strongly to exalt curiosity, and to give hopes of an ample harvest in the field of Sanscrit letters: namely, his translation of the Bhagvat-gita, one of the Epistles of the Mahabharatas, or great Indian poems, which has been transmitted in manuscript by the governor-general to the chairman of the Court of Directors in 1788, with a recommendation that it should be published, was printed accordingly at the expense of the Company, with an appended letter of Mr. Hastings before alluded to, in which that enlightened statesman took occasion to communicate his views on the encouragement necessary to be given by the government of India to the cultivation of languages and sciences, and the necessity of the Government being caused by the unremitted attention given to his studies and public duties, rendered necessary his return to Europe. At Bath in the following year he published an English translation of the 'Hitopadesha; or the Book of Fables,' from that Persian collection of fables, the French and English versions of which are known by the name of 'Fables of Pilpay.'

Not long after his death, Mr. Wilkins gave his last address to the Sanscrit and Arabic Societies, and will be found in the volume of the Society's Transactions of the year 1782.
afterwards he began to arrange the materials for a Sanscrit grammar, which he had brought with him from India; and at the same time he had collected a specimen of the same method which he had employed at Hoogly with the Bengalee types, he formed with his own hands a set of Devanagari characters in steel, made matrices and moulds, and cast the necessary type to contain the twenty pages of the grammar, when, in May, 1796, his house was burnt to the ground, and so suddenly that although his books and manuscripts were saved, together with the greatest part of the punches and matrices, the type had entirely perished. A new set of the type and the twenty pages had been sent to his friend the late William Mar- dden, Esq. [MARDEN], and is probably the only one extant. This misfortune, added to other circumstances, prevented the resumption of his labours till the year 1806, when, soon after the formation of the East India College at Hertford, the study of Sanscrit having become one of the most desirable branches of the system of education there established, Mr. Wilkins zealously aided this object, the grammar was speedily completed, new letters were cut, and in less than two years this, the greatest of Mr. Wilkins's works, was published.

In 1801 he had been appointed librarian to the East India Company. Under his fostering care the library and museum acquired a degree of interest which they had not before possessed; and became an attraction to visitors both native and foreign, who, in common with those connected with India continually revisiting thither, were not less gratified by the obliging attitude of the librarian, than they were astonished with admiration of his profound and extensive knowledge: an elegant testimony to this effect is to be found in the amusing romance of "Hadji Baba." In 1805 he became visitor and examiner of the students in the Oriental department both at Hailey-bury and at Addiscombe. Thence he returned to his duties here, and formed the duties of them, with scarcely any intermission, until his death, which occurred on the 13th May, 1836, within a few days of attaining his 87th year. To such a degree did he enjoy the facilities which his mind to the last, the end of his life bounded in a day's notes at Cambridge before the timely statue of Mr. Cockeral, who on his death, is made, at the request of the president of the Board of Control, a translation of a letter from the Imam of Muscat, and forwarded it to that minister. Sir Charles Wilkins was twice married, and left three daughters.

The published works of Sir Charles Wilkins, beside those already mentioned, are, a new edition of Richardson's 'Arabic and Persian Dictionary' (1806-10), and the roots of the Sanscrit language (1815). In Dalrymple's 'Oriental Repository' and in Dodsley's 'Annual Register' and Sakoontala, an episode of the Mahabharata; and in the 'Annals of Oriental Literature' another portion of a translation of the same great poem. To these may be added some papers in the early volumes of the ' Asiatic Researches,' and his ingenious translation of the Sanscrit arc 'The Institutes of Menu,' of which he had completed more than two-thirds, when he was induced to desist by the knowledge that Sir William Jones was engaged on the same work, and which the latter published in 1794. Mr. Wilkins had the honour of being a member of the Royal Institute of Paris, and of many other learned societies abroad as well as at home. In 1825 the Royal Society of Literature presented to him their gold medal, bearing the inscription 'Carolo Wilkino, Literatui Sanscriti Principii.' In 1833 George IV. conferred on him the honour of knighthood in the Guelphic order.

Residing generally in London, he had a large acquaintance with many of the literary and scientific men, and was one of that distinguished society, consisting of Rennell, Marsh- den, Wollaston, Young, and others of the same class, who so often assembled around the president of the Royal Society, Sir Joseph Banks; or one of that which met periodical at the club established at the expectation of Reynolds and Dr. Johnson, of which Sir Charles Wilkins was elected a member in the year 1806. His comprehensive mind was not less alive to the advances of science, the discoveries in the library, mechanics, and the arts, than to philology, and no man was more ready and liberal in imparting his knowledge to others.

WILKINS, WILLIAM, was born August 31, 1778, at Cambridge, where his father was a builder. In that university he received an academic education, being matriculated at Gonville and Caius College in 1796, and graduating as sixth wrangler in 1800. Having in the following year obtained a travelling scholarship to Italy and Greece; and almost immediately after his return, published his 'Antiquities of Magna Graecia,' imperial folio, 1807, a work rather unsatisfactorily executed and not very specially valuable, but it was one of the first made by him of his previous studies, and ambitious of giving his own university a classical piece of architecture, he should have postponed all other considerations to that alone. Enamoured of the study of the Grecian style, he seems to have thought that this style could be adapted to the occasion, nor how far the occasion required that the style would not admit of. Instead of endeavouring to adapt it, he merely applied it, just as he found it; and was not surprised to see it adopted for his purpose, merely from their columns, for in other respects they are merely so many neat houses; at all events, this college shows to pecular disadvantage at such a place as Cam- bridge. Neither does the building make amends in other respects, as a important and the accommodation it affords being very defective, although the cost has been enormous.

In the case of the East India College at Haileybury, built which he erected a few years afterwards, when he held the appointment of architect to the East India Company, in the resignation of the late Mr. Cockeral, there were at least no local associations to deter him from having recourse again to the pure Greek architecture; but it is some- where strange that, instead of endeavouring to improve upon such a splendid example, he should not have expanded it more than repeat the same design. He afterwards succeeded better when he had to adopt Gothic for the additions and alterations which he executed at the three colleges of Trinity (1822), Corpus (1823), and King's (1826) at Cambridge. While he had hardly taken his hand at all to the preparations for the elevation, he was also less fettered by those pedantic scruples which prevented him from treating the Grecian style with freedom, where it must either be entirely rejected or else be so limited as to lose all character. His freedom was for the actual occasion:

Greater freedom he did afterwards allow himself in the façade of University College, Gower Street, originally called the University of London, where he has not scrupled to introduce some new ideas into the principal entrance in order to keep the style. In 1835 the site of the office, the only part which remained in the metropolis, excepting the University Clubhouse, was purchased by the society for 12,000, and on it obtained a plan to raise a new building. The completion of the building was left to his successor, the Wren.

WILKINS, WILLIAM, was born August 31, 1778, at Cambridge, where his father was a builder. In that university he received an academic education, being matriculated at Gonville and Caius College in 1796, and graduating as sixth wrangler in 1800. Having in the following year obtained a travelling scholarship to Italy and Greece; and almost immediately after his return, published his 'Antiquities of Magna Graecia,' imperial folio, 1807, a work rather unsatisfactorily executed and not very specially valuable, but it was one of the first made by him of his previous studies, and ambitious of giving his own university a classical piece of architecture, he should have postponed all other considerations to that alone. Enamoured of the study of the Grecian style, he seems to have thought that this style could be adapted to the occasion, nor how far the occasion required that the style would not admit of. Instead of endeavouring to adapt it, he merely applied it, just as he found it; and was not surprised to see it adopted for his purpose, merely from their columns, for in other respects they are merely so many neat houses; at all events, this college shows to pecular disadvantage at such a place as Cam- bridge. Neither does the building make amends in other respects, as a important and the accommodation it affords being very defective, although the cost has been enormous.

In the case of the East India College at Haileybury, built which he erected a few years afterwards, when he held the appointment of architect to the East India Company, in the resignation of the late Mr. Cockeral, there were at least no local associations to deter him from having recourse again to the pure Greek architecture; but it is some- where strange that, instead of endeavouring to improve upon such a splendid example, he should not have expanded it more than repeat the same design. While he had hardly taken his hand at all to the preparations for the elevation, he was also less fettered by those pedantic scruples which prevented him from treating the Grecian style with freedom, where it must either be entirely rejected or else be so limited as to lose all character. His freedom was for the actual occasion:

Greater freedom he did afterwards allow himself in the façade of University College, Gower Street, originally called the University of London, where he has not scrupled to introduce some new ideas into the principal entrance in order to keep the style. In 1835 the site of the office, the only part which remained in the metropolis, excepting the University Clubhouse, was purchased by the society for 12,000, and on it obtained a plan to raise a new building. The completion of the building was left to his successor, the Wren.
While the National Gallery was incurring criticism, both well meant and meritorious, the architect entered into the competition for the new houses of parliament, in 1836; but his designs were the most extravagant of the three, and the very extravagant nature of his conceit led him to oppose, with great acerbity, the project of his rival. The remarks however attached to it by its author in the descriptive catalogue of the designs were in a tone that called attention to it there, and he immediately followed them up by *An Apology for the Designs of the New Houses of Parliament.* Americans 'were not long in noticing the excesses, and in his own profession he admitted very freely, and with no little bitterness of tone, both on the successful design and the conduct of the commissions. To annoyances and vexations of this kind succeeded a still more dubious event, the public admission of his eminence in his profession; for on the death of Sir John Soane, in 1837, he was elected to succeed him as professor of architecture at the Royal Academy, of which he had been a member in 1834. Yet while his requirements were more fully supplied than those of his more successful predecessor, the question was asked whether he would have proved a very competent instructor. His *Prohanciones Architectonicae,* the first part of which (the only one published) appeared just at that time, 1837, did not augur well for his future lectures. There was an absence of the right spirit and the absence of the breadth of view with which the plan of the building was executed, to make himself more practicable. His constitution had at last been greatly impaired by smart, and he had been visibly sinking for some time. He died at Cambridge, August 9th, 1839, on his way to visit the Cathedral. The remains were removed to the Corpus Christi, a part of the new buildings at that college erected by him, and which he considered his best work.

Among other structures by him are:—the Nelson Pillar in St. George's Park, Dublin, 1836; the Nelson Pillar at York; a statue of Major-General Hawick, in Hyde Park Corner, which is remarkable, and not unpleasantly so, for the tetrastylistic portico of square columns in its east front. Donnington Castle, the seat of Earl Moira, and a house for Mr. Forster, at Oswestry, are of a similar character, and as it is remarked by Mr. Rhead, in his *New Vitruvian Britannense,* that they are rather identical, the first being no better than *Strawberry Hill* Gothic, and the second a mere parody of Grecian Doric architecture. It is more probable that they were by Mr. William Wilkin, or Mr. William Wilkin; such, for by himself, must have been designed by himself and he went abroad.

Besides the literary works already mentioned, he published *Athensia,* or Remarks on the Buildings and Antiquities of Athens; *Edifices of Vitruvius,* containing those books relating to the Public and Private Edifices of the Antients, *Imp. 4to,* 1812, to which last it was his intention to add a translation of some of the other books; but though such translation was announced about two years before its death, it never appeared.

**WILL.** The notion of necessity has been explained in the article Necessary; it remains here to consider the question of the Will.

The nature in which this question has been involved is perhaps mainly owing to carelessness in the use of terms; and yet, however carefully we may select and use our terms in discussing this question, it has always been found very difficult to state it clearly. Harley puts the question, *the necessity of human actions, in opposition to what is generally termed free-will;* and he says, *by the mechanism of human actions, I mean that each action results from the previous circumstances of body and mind; and, in the more general term, from the causes which they depend on.* Thus, he supposes that by free-will is meant a power of doing either the action or its contrary, while the previous circumstances remain the same. If by free-will be meant a power of beginning motion, this will be a kind of the same thing, since according to the opinion of mechanism, as here explained, man has no such power; but every action or bodily motion arises from previous circumstances, or bodily motions, already existing in the brain, i.e., from vibrations, which are either the immediate effect of impressions then made, or the remote cause by means of which a certain action is determined. But if free-will be meant anything different from these two definitions of it, it may not perhaps be inconsistent with the mechanism of the mind here laid down. Thus if free-will be defined the power of doing what a person determines his wills to do—of deliberating, suspending, choosing, &c.—or of resisting the motives of sensuality, ambition, resentment, &c.—free-will, under certain limitations, is not only consistent with the doctrine of mechanism, but even flows from it; since it appears, from the foregoing theory, that volitions, and actions, are combinations of ideas, of existing and restraining affections, and of performing and suspending actions, arise from the mechanism of our natures. This may be called free-will in an essential and philosophic sense, in contradistinction to that which is opposed to mechanism, and which may be called free-will in the philosophical sense. This passage is not selected as being a peculiarly successful statement of the question, but simply because it shows with sufficient clearness of mind, belief under consideration, and that independently of the author's theory of vibrations.

The universal language and practice of mankind imply a belief in a kind of free-will. To deliberate, to choose, to act in pursuance of the choice, to act with knowledge, to act with consideration, are expressions in every man's mouth, and things within every man's ordinary experience, both of himself and others. Every man also supposes that another will choose and determine pretty much in the same way that he himself does, and that individuals and species, as a rule, that is, each man believes that every other man will be governed by motives, or will act according to motives, in the main pretty much as he would himself. When men act differently under the same external circumstances, the cause of the difference is supposed to be either insufficient, incorrect, or bad motives, or a difference in the circumstances, in which it is here supposed that there is no difference, but to some difference in the persons. We believe therefore that circumstances move men to act, and that what we have done is pretty much what we would have done if we had had the same motives, and exercised these various motives and giving the preponderance to one or another, and that different men possess and exercise this power in different degrees. This may be called, in a sense, a free exercise of the will, and every man, at least, is of sound mind, believes that he has this power, and is supposed by others to have it.

The belief that man possesses this power is the foundation of laws which forbid acts under certain penalties. All legislatures have believed that the knowledge that a certain act will produce a certain effect, or of the consequences of an act, may induce free-will, and has imposed on those who are disposed to do the forbidden act; that the persons who are by any motives led towards such act may, and as a general rule will, deliberate on the penalty attached to the act before they do it, who are the objects of the laws by a comparison of the advantage which they expect to derive from the act, with the certain penalty attached to it. Many persons do not violate the law, because they have been brought up in habits of uniform obedience to it, and therefore the penalties of the law have little or no effect upon their conduct; but it will hardly be disputed that the fear of punishment has some effect on many men, and is a motive which, operating on the mind and operating upon the mind, produces the constraint. The law supposes a power in men to determine how they will act; or, in other words, it supposes at least that motives can be presented to men which shall in some way and in some degree determine their conduct.

As the law is under the influence of motives, and that they have also the power of weighting motives, is universally admitted, and for all practical purposes it is immaterial to inquire any further. A man subjects himself to a certain discipline, he educates his children in a certain method, and legislators forbade freely to do a variety of acts—all acting under the belief that the discipline, the education, and the rules of law are so many motives, which, by constantly operating on the mind, will produce on the whole a certain line of conduct in those who are under them.

But it has been already said that the external circumstances or the motives being the same, two persons will...
often act differently under them. As the external motives are by the supposition the same, there is some difference in the persons which causes the difference of conduct. Under the same external circumstances one man will violate the law, and another will not: one will steal and rob, and commit murder, and another will not. It is generally the same, the circumstances under which the act is voluntary: that he could, if he chose, have acted differently. Practically, he who executes the law will not trouble himself with the question whether the act was his interest, or what his individual reasons for it were, when the circumstances under the circumstances: it is shown that such a person possessed the ordinary understanding of mankind, he will see no reason for remitting the punishment; because he believes that in most cases, if not in all, the penalty attached to an act will operate on future people free from it. The question of an absolute free-will, then, does not concern a legislator. It is enough for him to present the proper motives for acting or not acting in certain ways, if he believes that such motives will on the whole produce the conduct which he requires. Nor does the question of absolute free-will concern any other person who has to direct or operate upon others. If he believes that he can place such circumstances around persons or present to them such motives as will ensure a certain course of action, it is unimportant whether he believes that the course of action is necessarily determined by these circumstances, or by these occurring with other circumstances, or that the persons who are under their influence do in some way or another determine to act in the wish they are disposed to. But if we examine more closely any particular act of a man's life, suppose it to be an act which has about it all the marks of slow determination, in what sense can we say that this is an act of absolute free-will? The ordinary language of mankind, and the language of all mankind, when rightly analyzed, is the true exponent of universal opinion. Confused and perplexed as it often is, it contains within it implicitly the elements of all philosophy. Now when we once refer to antecedent circumstances as affecting or determining the choice, and present them on any one occasion, we give up the theory of an absolute free-will, for we make every act of will depend, in some degree at least, on something prior to it, and thus we have an infinite chain of events, and consequently we find ourselves engaged in an inquiry which is beyond the reach of our capacity. Thus it, as Hartley says, "by free-will be meant a power of beginning motion, no person can consistently with his own nature, and that of others maintain this proposition; if he does, he will contradict himself almost as often as he speaks.

Human actions, then, are, in some degree at least, subject to fixed laws to which human actions are subject. Every human action has its antecedent, on which it is in some degree depends; but whether every human action is as necessary, in the sense in which Hume explains the term necessary, as the other phenomena which we see, is precisely in dispute. (Hume, Essays, "Of Liberty and Necessity.")

When it is said that every event and every human action has its antecedent on which it depends, it must not be understood that it is meant, here at least, to maintain anything else than this. Such antecedents are events which, according to our experience, precede the given event uniformly, or at least with sufficient uniformity to generate in our minds the notion of a certain order or continuity; for though any given antecedent event is called the cause of any event which uniformly follows it in our
by analogy such terms as are applicable only to our own limited capacities: and we say that he wills generally that all things shall be as they are, but that he disapproves of some. That he permits man so much liberty of action as to render it necessary for society to be vigilant against the evil doers who would disturb its repose, is no more an imputation upon his goodness than that he permits fire, tempest, and war and pestilence and famine to thin the numbers of mankind. So far as concerns those who suffer, it is the same thing. He does not allow all the rest of the world to walk on the earth free and uncontrolled, man, or from causes over which man has no control. It is consistent with all experience to say that the Deity has willed that man shall suffer pain both through the agency of other men and through the agency of his fellow-men. Now if we shall assume that God could have willed in a sense in which many persons understand it—which would, according to their notions, exclude all pain and suffering—whatever misery happens through man's misconduct must be due to an evil power outside of man, to an absolute free-will, and sometimes exercising it in a way different from the Deity's wishes. There is no evading this difficulty. An absolute free-will in man or in any other being is inconsistent with the omnipotence of the Deity as we have determined, shown by that which we at our observation of the mode in which man is operated upon by motives and circumstances. But there is nothing which prevents us from attributing to man, as we do in our daily expressions, a power of determining his acts, under given circumstancess, that is the correct and is not in another direction and in a wrong in a preference to a right direction. And it is further admitted by the universal language of mankind, that the same man who acted wrong under one set of impulse might and would have acted right if he had been influenced by the right action; if he had been influenced by the right impulse, it is said, is also admitted, and oftentimes are instantly and in a wrong preference to a right direction. And it is M. That a man may reason discipline himself, that, in any given circumstances, he should have acted before he died and that he may have motive power, a command which shall enable him to act in the right direction, a power which Hartley speaks of in the passage at the head of this article. But if some men can do this, all cannot; and even in the case of him who can do it, we may say that he is more than half, and if it is motive interest. But circumstances over which he had no control. Man's will is circumscribed by the constitution of things, of which he is a part. He is placed in circumstances in which he is operated upon by various motives to act. If it is said that a man who has made his mind he died wrong, that is as true a man the power of bequeathing the whole of his personal property. And now, by the 1 Vict. c. 26, for the amendment of the law with respect to wills (whence the Deity has then enumerated with respect to wills are repealed, except so far as the same acts of the Deity are sufficient to the extent of wills or estates par autre vie to which this act does not extend), it is enacted that it shall be lawful for every person to devise, bequeath, and dispose of, by his will, executed as required by that act, all real and personal property except such a will as might have been made in a manner not contrary to the law, extended equally to the bequeathing of personal estate, except that infants of a certain age, namely, males of fourteen and females of twelve might dispose, by will, of personal property; and that by the 12 Car. II. c. 21, a 6, a father under twenty-one might, by a will appoint a guardian to his children. But now, by the second section of the new Wills Act, no will made by any person under the age of twenty-one years is valid; and no will made by any married woman is now valid, except such a will as might have been made by a married woman before the passing of the new Act. The disability,
of a married woman is not absolute. She may make a will of her personal property with the consent of her husband, which will be operative if she survive her. The validity of a husband's will depends upon the state of his mind at the time of making it. Persons born deaf and dumb are presumed to be incapable of making a will, but the presumption may be rebutted by evidence. Blindness and deafness alone do not in themselves produce incapacity. Traitors and felons are incompetent to make wills from the time of their conviction, and it seems that an outlaw, though it be but a child of four, is incapable of making a will. He is personal property till his outlawry is reversed. Deeds of lands by aliens are at least voidable, the crown being entitled, after office found, to seize them in the hands of the devisee, as it might have done in those of the alien during his life.

The testator's will is the supreme act of government, and was subject to exceptions. Customary freeholds and copyholds were not within the Statute of Wills, and therefore, unless where devisable by special custom, could in general be passed only by means of a surrender to the use of a will. By custom, if the lands were supplied in cases where it was a mere form, but the act did not apply to cases where there was no custom to surrender to the use of a will, nor to what are called customary freeholds. [MANOR.] Again, a devisee or surrenderer might not be present before admittance, though an heir-at-law might. Conditions were not devisable, nor were rights of entry or action, nor contingent interests when the person to be entitled was not ascertained; lands accrued after the execution of the will also did not pass by it. The execution of a will is in general by three witnesses, or by subscription in the presence of the testator, and is necessary. The presence of witnesses required by the power under which the appointment is made. By the 11th and 12th sections, it is declared that the act is not to affect the wills of soldiers or actual service or of mariners at sea, which are to remain subject to the particular privilege given by the 11 Geo. IV. and 1 Wm. IV., c. 20. Questions sometimes arisen as to what amount to publication of a will, section 13 expressly enacts that no other circumstances depend. It is a will made in France and written in French, of lands in England, must contain expressions which when translated into English would properly designate the lands in question, and must be purchased according to the forms required by the English law. For the latter reason lands in England belonging to an English subject domiciled abroad and dying intestate, will descend according to the English law. With respect to personalty, on the other hand, in cases both of domicile and of estate, the rule of the domicil affords the rule for the construction of the will and the distribution of the property. Thus, if a British subject becomes domiciled abroad, the law of his domicile at the time of his death would be the rule which the English courts would follow in determining the validity of his will and in administering his personal property in England, and vice versa in the case of a foreigner dying domiciled in England. The question of domicile is one more of fact than of law, and cases sometimes arise where it is matter of difficulty to establish the actual domicile of the testator at the time of the death of the party. Consequently what rule is to be followed in the distribution of his personal estate. Where an Englishman domiciled abroad has real property in England, he ought, on account of the difference of the doctrines in the two countries, to be regarded as having real and personal property, to make two wills, one solely executed according to the English law, devising his real estate, and another framed according to the law of his domicile disposing of his personal property. A will being in all cases whatever, a revocable instrument. It was an established rule of law that the will of a sane sole was revoked by her marriage, but marriage alone was not considered as a revocation of the will of a man; though marriage and the birth of a child, whom the will would undermine, conjointly had that effect. In these circumstances together produced such a total change in the testator's situation, that it could not be presumed he could intend any previous disposition of property.
and no annuity or other alternation made in or out of the will, after execution is to have any effect except as far as the words or effect of the will previous to the alternation cannot be made out, unless the alternation is executed as a will, such execution to be in the margin opposite or near to the alternation, or to a memorandum referring to the alternation. By the Statute of Wards, personalty is to be deemed vested immediately, but it was not necessary that he should sign in their presence, whereas by section 6 of that act a mere revocation in words must have been signed by the testator in presence of witnesses, but they were not required to sign in the margin or on a memorandum. The intention to destroy is what the law regards, and which it requires should be expressed by one or other of the modes pointed out in the act. The 23rd section alters the law as to how far the direction that the will should be revoked should be expressed, making it expressive, and a cancellation by drawing lines across the whole or part of the will. These acts will now be of no effect unless properly executed and attested. By the 23rd section no conveyance or other act made or done subsequent to the death of the testator, except an act of revocation, is to prevent the operation of the will upon such estate or interest as the testator has power to dispose of at the time of his death: and by the 24th section every will is to be construed with reference to the real and personal estate of the testator at the time it is to speak and take effect as it had been executed immediately before the death of the testator, unless a contrary intention appears on the will.

The 22nd section of the act provides that no will or codicil, or any part thereof, which shall have been in any manner revoked, shall be of the estate otherwise than by the re-execution thereof, or by a codicil executed in manner required by the act, and showing an intention to revive the same, and when any will or codicil which shall be partly and not wholly revoked, the revocation is not to extend to such parts as had been revoked before the revocation of the whole, unless a contrary intention appears. Under the old law, if a second will or codicil which revoked a former will was afterwards cancelled, the former one had been destroyed, and was not to be revived. It had previously been determined (4 Ves., 610) that a subsequent codicil, merely for a particular purpose and confining the will in other respects, did not amount to a republication of parts of the will revoked by a former codicil. This section extends in a particular case where a will had been first partially and afterwards wholly revoked. The rules of law as to settlements of real or personal estate by deed or will have already been explained. [Surety, Estates of real or personal estate]
If the testator had no other lands answering the description, a general devise would have been a good execution of the power. But it was otherwise if he had any other lands which would satisfy the terms of the devise. The enactment applies only when the testator has a general power of appointment. When the power is limited or special, it seems that the old rule of construction will still hold. As to personalty, the testator's rule was, they were to be construed to reference to the person, on the somewhat unsatisfactory ground that as any person must be supposed possessed of some personality, there was enough to make a general bequest operative without reference to the property, as where the power is not special. It seems that the old rule must still prevail where the power is special or limited. By the 28th section a devise of real estate without words of limitation is, unless a contrary intention appear by the will, to be construed to pass the estate. This clause infuses by very considerable alteration of the old law, under which, in accordance with the doctrine that the heir was not to be disinherited by implication, it was settled that a devise of lands without words of limitation conferred on the devisee an estate for life only, even notwithstanding the appearance of a contrary intention in other parts of the will. The 29th section enacts, that in any devise or bequest of real or personal estate the words 'die without issue,' die without leaving issue,' or an issue, or that the power shall be construed to mean a want or failure of issue at the time of the death, and not an indefinite failure of issue, unless a contrary intention appear; except in cases where such words import, if no issue died when the devisee should be a person who shall live to attain the age or otherwise answer the description required for obtaining a vested estate by a preceding gift to such issue. Under the old law, when a testator gave an estate to A and his heirs, if A died without issue, B, though his meaning in most cases was that B should have it unless A had issue living at the time of his death, the word 'issue' was held to comprise descendants of every degree existing at any distance of time, and the courts would construe it as meaning that while the estate was real estate, A took an estate tail and acquired the absolute dominion over the property [REMAINDER], and where it was personally the ulterior disposition to B was void for remoteness [SETTLEMENT].

By the 28th section every devise of real estate (not being a right of presentation to a church) to a trustee or executrix is to be construed to pass a fee simple, unless where a definite term of years or an estate of falsehood less than a fee simple is expressly given to him. And by the 32nd section trustees under an unlimited devise to their testator, where the trust may endure beyond the life of a person beneficially entitled for life, are to take the fee. When the limitation in a will was made to a trustee by way of use, he took the estate by the operation of the statute and for uses, without reference to the nature of the trust. But in other cases the question was determined by the intention of the testator, as collected from the nature of the trust; and the trustee was considered to take only that quantity of estate which the exigencies of the trust required. Such a rule of construction was obviously very difficult operation, and it was often not easy to determine in whom the fee was vested at any given period, and therefore who were the proper parties to deal with the property and to join in a court of chancery for its restitution or retention in the hands of the assignee. This last-mentioned section will in a great measure remedy this inconvenience.

It follows from the nature of wills that the devises and bequests contained in the will are to be construed as to failure from the death of the devisee or legatee before the testator. This is called the doctrine of lapse. It applies equally to devises of real estate and to bequests of personalty. It is a general rule that words of limitation to heir at law or executor are to be construed as to failure before the death of the testator, they being considered not as words of gift, but merely as indicating the legal devolution of the property. When the gift is to several persons as joint tenants the gift is consumed before the testator's death. In preventing lapse in case of the devisee or legatee dying before the testator, they being considered not as words of gift, but merely as indicating the legal devolution of the property. When the gift is to several persons as joint tenants the gift is consumed before the testator's death. In such an event there can be no lapse; for as joint tenants each is the legal owner of the whole, any one existing at the death of the testator will be entitled to the entirety. The same is the case where the gift is to a class, unless where the individuals of the class were ascertained before the lapse. T devices have been introduced into the law of lapse by 32d section, the 24th act. The 32d section of the 24th act shall not lapse, but that where the devise is in tail during the life-time of the testator, leaving issue, the devise shall take effect as if he had died immediately after the death of the last preceding in tail, and, by the 33rd section, gifts to children of the testator who shall die before the testator, having issue living at the testator's death, are not to lapse, but, if no contrary intention appear by the will, are to take effect as if the personalty operated upon all the property of that kind belonging to the testator at the time of his decease, there could obviously be no intestacy with regard to any part of the personal estate while there was a valid residuary bequest. The same will now be true of devises in tail in which there is a valid residuary devise, so that there will no longer be room for many of the questions that arose as to whether the residuary devisee took beneficially or as a trustee, and as to the devolution of real estate directed to be sold.

It should be observed that where an ambiguity exists on the face of a will, or, as it is technically termed, is patet, parol evidence cannot be admitted to remove it, because the will is not to be construed to the extent to which the 32d section would require it. Where the ambiguity exists in the will, or arises before the circumstances disclosed when an attempt is made to carry the will into effect, it may be removed by reference to the surrounding circumstances in which there is a valid residuary devise, so that there will no longer be room for many of the questions that arose as to whether the residuary devisee took beneficially or as a trustee, and as to the devolution of real estate directed to be sold.

(Powell On Devises, and Jarman's Notes to Bythow's Precedents, Wills.) [EXECUTOR; LEGACY.]

WILL. (Scotland.) The right of bequest in Scotland is confined to moveable personal or personal property. It does not extend to immovable real property, and cannot, therefore, be exercised by devise or devises, nor can it be exercised by testament or testaments, fixtures, those appurtenances of a family mansion (such as the pictures, plate, and library) which are called 'heirship moveables,' the machinery in mines and manufacturers, the stock on farms, and every description of personalty which was subject to the right of the granter. In Scotland, Settlements may be made of heritable property in the manner which will be described below, but it is a principle of the greatest importance, and one the neglect of which is often productive of the most serious consequences, that no such settlement can be made in the form of a will. All persons of sound mind above the age of puberty (14 males, and 12 in females) may execute wills; and persons under guardianship, as wives and minors who have curiae or both, may, with the consent of their guardian, settle and dispose of their own property. Until very lately the will of a bastard was ineffectual; the moveable goods of such a person, lapsing to the crown on his death, were distributed by a gift in exchange; but this peculiarity has been abolished by S. 81, T. V. (1819). Executors of testators may settle property on residuary legats, or may settle it in the presence of two witnesses who bear testimony to it. It is valid to the extent of a hundred pounds Scots or £8, 8s. 8d. sterling; and if the bequest should exceed the sum, the legatee may recover to the extent of the hundred pounds Scots. A will, sufficiently formal in all points to prove its terms and its date, must be executed in the following manner:—The granter's usual signature must be given at the end, and, if there be more than one sheet, on each sheet: the usual practice is to sign each page separately. The two witnesses, or one witness in the case of one witness, must sign the will, or the descending name of it, and the surname or its initial letter or it, above, and the surname or its initial letter below. He must either sign in the presence of, or show and acknowledge his subscription in the presence of, witnesses, who must be witnesses of each other, and be over the age of 21 years. The witnesses sign the will at the end, each placing after his name the word 'witness.' The will must terminate with ' testing clause,' setting forth that the granter has signed the deed in presence of the witnesses, who have subscribed their names and signed the same; or that each bequests to others, at a certain place on a certain day. The testing clause must contain the name and description of the writer of the deed, the number of pages it consists of, the number of words written in ensuere or interlined, and all the objectionable matters. If the will contains these formalities of which the absence is fatal to the deed—often in which it will throw the onus probandi on the holder. Where the will is holograph, or written by the grantor...
It does not require to be attested; but if it be tested, it in the first place does not prove itself holograph, and the statement that it is in the writing of the decedent must be proved by evidence to be true; and, secondly, it does not own date; and if there be any other title, it will be presumed to have been granted a time as will give that title the preference. If the mansion were made executable, it also relieves authority in presence of two subscribing witnesses, a sign for the testator, and describes the transaction tarae doquet. A clergyman of the Established Church may act as a notary for the signing of its title. The testator must be old enough to do so; and if there be no one named, or is supplied by operation of law. Wills executed by persons domiciled out of Scotland, if they be secondly, the testator who would carry such property in the place where they were executed, will be effectual to convey moveable property in Scotland; but no will, whatever be the law of the place where it is made, can dispose of heritable property in Scotland. The last dated will is the effective one, and all other wills considered as revoked by it in so far as they are inconsistent with it.

The peculiar feature of the law of Scotland out of which arises the circumstance that heritable or real property cannot be bequeathed is, that no deed conveying such property is a nullity if the will of the testator is not executed. Such 'dispositive terms,' or terms making over the property at the moment of the signing of the deed. Thus the terms 'I grant, convey, and make over,' are sufficient to carry heritage; but the terms 'I give, or hereinafter make,' will not carry property in Scotland, and at the time of death, it might not be turned with it to another person unless that person were accepted as a mutual by the feudal superior. A conveyance not intended to take effect until after the cedent's death (for instance, a devises disposition,) and the method of creating a settlement of landed property was constructed on the forms by which the feudal usages were gradually adapted to the conveyance of land from a seller to a purchaser. A deed of settlement relating to landed property is a testamentum properly so called, for to accomplish the purposes of a virtual bequest, the following methods have been adopted by conveyancers:—

1. the granter may convey to himself, with a 'substitution' or remainder to his destined successor; 2, he may grant a deed of remuneration, reserving to himself the life rent; 3, he may grant such a conveyance, reserving power to alter. It is of the nature of a conveyance of land that to be effectual, delivery of the deed to the assignee, or an equivalent, must have taken place, and thus a settlement of land to be effectual must be completed by the person, and if one or more for his behoof, or must have been entered in a public register, or must contain a clause dispensing with delivery. The formalities necessary to accomplish the conveyance of landed property is the act of the party who transacts the conveyance.

The term 'freehold' is used for real property in Scotland, but with this difference, that in the settlement of heritable property, if the party cannot write, the deed must be executed by two notaries for four witnesses; and in this case a clergyman cannot act as notary. To be an effectual deed, a settlement of landed property must also contain authority for completing the feudal title to the property, and this authority will vary with the nature of the holding. When however the holding is in the Roman people, this will be in clear terms a conveyance de praebenda, although the formalities necessary for completing the feudal investiture be omitted, and it be thus insufficient of itself to create the estate, it may give a right of action to compel the heir-at-law to tender a seisin, or a proper compensation. In general, if the person is dead, he is by that act bound to make good its provisions in favour of all other persons. Thus, if the deed be in the form of a bequest, and in itself incapable of carrying heritage, if it convey moveable property to the heir which he would not have been entitled to, he is bound, if he take advantage of it, to fill its destination of the heritage. No settlement of heritable property to the prejudice of the heir-at-law can be validly granted on a death-bed. Three elements are necessary to a valid disposition on a death-bed: 1st, that the grantor was ill of the disease of which he died when he granted the deed; 2nd, that he died within sixty days after executing it; and 3rd, that he did not go to church, or to a market, unsupported, during the sixty days. The act 7 Wm. IV., and 1 Vic., c. 56, and the other enactments relating to wills in England, do not apply to Scotland.

WILL, ROMAN. A Roman will was called Testamentum. Testamentum was defined by the jurists of the Imperial period to be a legal mode of a man's declaring his intention in due form, to take effect after his death. The phenomenon was one of a very ancient age.

The power of making a Roman testament only belonged to Roman citizens who were sui iuris, a rule which excluded a great number of persons: those who were in the power of another, as sons not emancipated, and daughters; Imperium, and were therefore per immuniti or under the protection of others; and, as a general rule, all women. The circumstances under which a woman could make a will were peculiar; and they would require a very particular statement. A male of the age of twenty years, because he was under some special incapacity, could make a valid will. A female, so far as respected age only, acquired this capacity on the completion of her twelfth year.

Originally Roman citizens made their wills at Calata Comitia, which were held twice a year for this purpose. It is not said that these wills were made in writing; and it is here assumed that they were made at the Calata Comitia only for the purpose of securing the proper evidence of the testator's intention. It has been maintained by Niebuhr, that the rules in Calata Comitia may be compared to the Gentes might give their consent to the testamentary disposition, but this conjecture is not supported by evidence. If a man died in the interval between two such Comitia, he must have made a testament written. But wills could also be made In Procinetu, who were done by the soldier under arms and in presence of the enemy. Another mode of testamentary disposition was introduced, apparently for the purpose of preventing intestacy. If a man, says Gaius (ii. 102), had neither made his will at the Calata Comitia nor In Procinetu, and was threatened with sudden death, he transferred, by the form of mancipatio, his familia, that is, his patrimonium, to a friend, and told him what to give to each person after his death; this was called the testamentum per ae et libram, because the transfer was effectuated by mancipatio. Thus it appears that the testamentum per ae et libram was a formal transfer of the property during the lifetime of the owner to a person who undertook to dispose of it as he was directed. As it was a substitute for the testamentum for Calata Comitia, it is a probable inference that it only differed from the testament made at the Comitia in wanting that publicity. The two old forms of testamentary disposition, adds Gaius, fell into disuse, and that per ae et libram became the common form of will. Originally, the testator himself could dispose of his estate (familiae emptor) occupied the place of the heres at a later time; when Gaius wrote, and long before his time, the old form of testamentary disposition was retained as an exception to the testator's right to dispose of his estate, as being too inconsistent with the duties devolving upon the heir and executor. The form of testamentary disposition was then made into a form which would carry into effect the testator's intention. The formal purchase was only retained out of regard to antient custom, and the institution of a heires became necessary to the validity of a will.

The form of testamentary transfer per ae et libram is described by Gaius (ii. 104). As in other acts of mancipation, so in this, there were five witnesses of full legal age (puberes). These five witnesses are considered by some modern writers to be the representatives of the five classes of heres, and that the confirmation of the dispositions was rendered valid by the consent of the five classes, so here it was rendered valid by the presence of the five witnesses. In this article it is supposed that they were present as witnesses.

Written wills, as already observed, were not necessary, for neither mancipation nor the institution of a heres require a writing. But written wills were the common form during the later Republican and the Imperial period. Wills were written in wax tablets, and a piece of wax, called 'era' (wax) is often used as equivalent to tabula. A Roman will was required to be in the Latin language until a.d. 439, whilst it was enacted that wills might be written in Greek. A Roman will in the later periods was sealed and signed by the witnesses, and in some cases by the testator. The will was marked with a ring or something else on the wax, and the names were added. The seals and names were on the outside, for, according to the old law, there was no occasion for.

P. C., No. 1729.
the witnesses to know the contents of the will. The old
practices of the testator to show the will to the witnesses,
and to call on them to witness that what he so presented to
them was his will. It was not unusual for a man to make
several copies of his will, and to deposit them in some safe-
keeping. Augustus, the emperor, made two copies of his
will (Sueton., aug. 101); and also his successor Tiberius
(Sueton., Tib., 76). The Vestal Virgins were often the
keepers of wills, or they were deposited in a temple or
with a friend. At the opening of the will the witnesses or
the greater part, if alive and on the spot, were present,
and after acknowledging their signatures the will was
opened.

It has been mentioned that in order to make a Roman
will valid, it must appoint or institute a heres. The heres
was a person who represented the testator, and who had
the legacies which were left by the will. He stood in the
place of the familiar empor, or formal purchaser of the
property in the old form of will. A heres might be appointed
in such words as follow: "Titius heres esto," "let Titius be
my heres," or "Titum heredem esse jubeo," "I will Titius
to be my heres." Generally all Roman citizens who could
make a will could be heredes; but persons could be
heredes who could not make a will—slaves for instance,
and others who were not sui juris.

The case of wills and other instruments was punished by
severe penalties under a Lex Cornelia.

The development of the Edictal or Praetorian law at
Rome introduced a less formal kind of will. If there were
seven proper witnesses and seven seals, and if the testator
had left his will in the form prescribed, and if the
will and at the time of his death, the edict dispensed
with the ceremony of mancipation and gave to the heres
or heredes the bonorum possessio. This mode of testa-
mentary disposition existed as one could either make his will by the civil
form of mancipation, or he might make it after the praetor-
ian form with seven seals and seven witnesses, without
any mancipation. The form of testamentary disposition by
mancipation is ultimately supported by the most ven-
ient praetorian form. The legislation of Justinian
required seven male witnesses of proper age and due
legal capacity; and it was sufficient, if the testator de-
clared his will orally before these witnesses.

A Roman will, as already observed, was valid if the
testator had a disposing power at the time of making his
will and at the time of his death. It follows that his will,
though made at any time before his death, was sufficient
to dispose of all the property that he had at the time of
his death. The English rule of law was established in the case
of an English will by the recent act (1 Vic., c. 20) so to
real property; it always applied in the case of an English
will to personal property. But an English will is valid
if the testator subsequently loses his disposing power
for any reason if he become insane. A Roman will was not
valid under such circumstances; and it also became invalid in
other cases.

In order to render a Roman will valid, it was necessary
that the heredes sui of a man (his sons and daughters who
were in the class of heredes sui) should either be appointed
heredes or should be expressly excluded from the inher-
tance. A will which was illegal at the time of being made
was testamentum instiugum, that is, 'non jurum factum,' not
made in due and lawful forms. A will which was unjustly
became invalid; it might become ruptum (broken) or
irritum (ineffectual).

A second will duly (jure) made rendered a former will
invalid (ruptum); and it was immaterial whether the second
will was made within or without the year. The
rendered a former will of no effect, and the testator died
testate.

If a testator sustained a capitis diminutio after making
his will, that is, if he lost any part of a Roman
citizenship, it was essential to give him a full testamentary
power, the will became irritum, ineffectual. A prior will
might become Ruptum by the making of a subsequent
will; and such subsequent will might become irritum in
valid. By chance, if there was no heres to take
under the second will.

Though a will became Ruptum or Irritum, and con-
sequently lost all its effect by the Jus Civile, it might not
be entirely without effect. The bonorum possessio might
be granted by the Praetorian law, if the will was attested
by seven witnesses, and if the testator had a dispos-
ning power in the proper forms required by the Jus Civile
had not been observed.

The rule of Roman law which required heredes sui to be
expressly exheredated applied to posthumous children.
If a suus heres was born after the making of the will, and was
not recognised as having succeeded in due form, he
would become Ruptus. This rule of law was thus expressed:
"adscriptum rumpitur testamentum." There were the
cases in which a will might become Ruptum by a qua-
dratagnation.

A testament was called Inoficiosum when it was made
in due legal form, but not "ex officio petita." When
a man did not give the heredita, or a portion of it
to his own children or to others who were in a near
relation to him, and when there was no sufficient reason
in passing them by, the persons so injured might bring
an action called Inoficiosi Querela. The persons who could
maintain this action were particularly defined by the le-
alisation of Justinian. If the Testamentum was deduced to
the competent authorities to be Inoficiosum, it was
ascended to the amount of one-fourth of the heredita, which
was distributed among the claimants.

The ground of the Inoficiosi Querela is explained by
Savigny (System des Heutigen Röm. Rechts, ii. 12), who
in his nearest kin, it was presumed that such person had
merited the testator's disapprobation. If this was so,
and it was considered that the testator had by his will due
them a wrong, and the object of the action was to
request a redress. In the cases of the testator's will,
never was the establishment of the complainant's claims.
to which the obtaining of part of the testator's property
was a subsidiary means. The expression Testamentum is
of officius form was used by the Republicans and in Quintus,
but it is not known when the Inoficio was introduced.

A Roman codicil (Codicilli, for the word is not used in
the singular number till a late period under the Empire
was a testamentary disposition, but it had not the full
effect of a will. It was made in the same capacity as
heres. Codicilli were often inserted in a will to make
the provision for their heirs, as it was not uncommon for
the heirs to be the sons of the testator or of a near
relative, who was appointed to be a father figure in the
life of the testator. Codicilli were also used to make
provisions for a religious endowment, or to provide for
the support of a dependent.

The subject of Roman wills is of great extent, and it
involves questions of considerable difficulty. The author
authorities and the works of the learned have been made use
of in this article, to which may be added Ulpian, Fragmenta, tit. 20; Dig., 23, tit. 7; &c.;
Ep., ii. 16, which has been sometimes misunderstood.

Codicilli were originally informal writings; it was
not necessary to prove that they were by the testator.
The later Roman law required codicilli which were in writing to
have five witnesses, who subscribed their names to the
codicilli.

to London for the purpose of further improvement, and was about to settle there, when a relative in a good practice at Darlington died, and Willan became his successor. He remained at Darlington about a year, and he returned to London in 1782. During the time he was at Darlington he analysed the sulphureous mineral-spring of Croft, and published the result in an octavo volume, with the title 'Observations on the Sulphur Water at Croft near Darlington.' A second edition of this work was published in 1798. In this work are descriptions of the peculiar forms of vegetation that inhabit various parts of the waters. The chemical analysis of the waters is not to be depended on, having been made at a time when analytical chemistry could ensure little accuracy. He recommends these waters for the cure of some skin diseases, and perhaps here may be found the germs of inquiry that led to his future labours.

In 1783 the Public Dispensary in Carey Street was opened, and Willan was made physician. In 1789 he was allowed to open the Dispensary, and in 1790 he published a work on the Practice of Medicine. This work was illustrated by coloured plates of the various diseases which were described in the latter part of the 18th century. The first part was published in London in 1798, and contained the first order into which he had divided the several diseases of the skin. The second order, scaly diseases of the skin, was published in 1801. He did not live to complete this work. Two more volumes appeared in 1805-7, containing a part of his third order, the rashes, in which the varieties of scab, itch, and the like, are comprehended. The remainder of the rashes and the Bulla, or large vesicles, was published in 1808. The subject of vaccination having excited great interest, Willan was induced to publish a volume on this subject out of the regular series of his work entitled 'Diseases of the Skin.' In this work he gave a full account of Jenner's discovery, the cow-pox, also of the chicken-pox, and of other cutaneous diseases which might be confounded with the vaccine disease. The remaining portions of the work, including those of measles, on which he had been the most active, were not published as a completion of Dr. Willan's work; but all the materials having been committed by him to the care of Dr. Bateman, were afterwards published in a work entitled 'Diseases of Cutaneous Diseases, exhibiting the characteristic appearances of the principal genera and species comprised in the classification of the late Dr. Willan, and completing the series of engravings begun by that author,' London, 1810. This work was entitled 'An Enquiry into the Origin and History of Cutaneous Diseases,' and its application to a large number of cases, Willan did more for the advancement of the knowledge of the diseases of the skin than any previous writer, and laid the foundation for the successful labours of Bateman, Rayer, and subsequent authors.

Besides this great work, Willan published several papers in Journals and Transactions, upon various professional subjects. During some part of the time that he was connected with the Dispensary in Carey Street, he published monthly reports of the cases, with reservations. These reports contained much valuable information, and those from 1796 to 1800 were published in a separate volume, with the title 'Reports on the Diseases of London,' London, 1801, 12mo.

In the early part of his life he published a little volume entitled 'History of the Ministry of Jesus Christ, combined from the Narrative of it in the four Evangelists.' This was published in 1789, and a second edition, with notes and observations, appeared in 1786. Willan was fond of antiquarian pursuits, and read several papers before the Antiquarian Society, of which body he was elected a fellow in 1791. One of the most elaborate of his papers was an essay on the practice of Inflammation by need-fire, a practice which still continues in some of the northern counties of England. He was elected in 1809 a few years before the Royal Society.

During the latter part of his life he resigned his public situations. He took an active interest in the establishment of the Fever Hospital, and was made one of its first physicians extraordinary. His health, which never was strong, began to decline in 1810, and his friends persuaded him to embark for Madeira, where he died on the 7th of April, 1812.

At the time of his death he was engaged in investigating several points connected with the antiquities of medicine. Among other communications which occupied him was the nature of the ignis sacer: the evidences of the prevalence of small-pox, measles, scarlet-fever, and other epidemic diseases amongst the ancients; the history of leprosy, and also of lues.

Bateman, 'Memoir of Dr. Willan,' in 32nd number of Edinburgh Medical and Surgical Journal.'

Willdenow, Carl Ludwig, a botanist, was born in 1768, at Berlin, where his father was an apothecary. He was sent to a grammar-school, and then became a student in medicine at Halle, whence he proceeded to Langensalza, for the purpose of studying chemistry in the laboratory of Wiegell. He took his degree of Doctor of Medicine at Halle, and returned to his native city, and, having gained considerable success there, he was sent as an observer, and a good practical physician; and his classification of the diseases of the skin must ever be regarded as a great step for the advancement of the knowledge of the forms of disease.

WILDERNW, CARL LUDWIG, a botanist, was born in 1768, at Berlin, where his father was an apothecary. He was sent to a grammar-school, and then became a student in medicine at Halle, whence he proceeded to Langensalza, for the purpose of studying chemistry in the laboratory of Wiegell. He took his degree of Doctor of Medicine at Halle, and returned to his native city, and, having gained considerable success there, he was sent as an observer, and a good practical physician; and his classification of the diseases of the skin must ever be regarded as a great step for the advancement of the knowledge of the forms of disease.
the rarest plants growing in Europe. Willdenow corresponded with most of the botanists of his day, and from Klein he received plants from India; from Humboldt and Bonpland, those of America; from Labillardière and Smith, those of New Holland; and from Desfontaines, those of the coffee plant. Thus, in 1794, 1200 species he found growing in the garden. He left 6000. He also collected a large herbarium, consisting of above 20,000 species of plants.

The great work of the life of Willdenow was his 'Species Plantarum' of 1753. He commenced this work in 1757, and continued publishing it at intervals till 1810, when his health became so enfeebled to enable him to go on. He proceeded as far as the first part of the fifth volume, which contained descriptions of the species of the order Filius. A second part of the fifth volume, including the mosses, was published by Schwägrich in 1830; and Link, in 1824, published two parts of a sixth volume, including the Fungi, Hyphomycetes, and Gymnomyces. This work was the most important one of its day for systematic botany, as it included descriptions of all species that had been described since the first publication of the 'Species Plantarum' by Linnaeus. The first volumes of the book are not so well executed as the last, which is easily accounted for when the different position in which the author was placed and the number of volumes. There are also many manifest errors in the references to works, and in the quotation of synonyms, which diminish its value, and which have produced some very severe criticisms. It is possible that some of the magnitude of the work was the last high fault, there was nothing to supply its place till the publication of the 'Prodromus' of D' Candolle, and where this is incomplete, the aid of the 'Species Plantarum' of Willdenow is called for. The whole work is arranged according to the Linnaean system. From 1800 to 1809 Willdenow published at intervals descriptions with coloured plates of plants growing in the Botanic Garden at Berlin, under the title 'Hortus Berolinensis,' Berlin,folio. He has published many extemporal papers to various journals and Transactions of societies.

In 1811 Willdenow went with his family to Paris for the purpose of studying and describing plants in the collections there. He however was able to effect little, on account of his health, and he returned to Berlin, where he died on the 10th of July, 1812. He was a quiet reserved man, and too little communicative to make an efficient teacher, and comparatively few of his pupils have distinguished themselves as botanists. He was an ardent admirer and horticulturist, and his system, does not appear to have been cognizant of those principles of classification or the physiological facts that have latterly contributed so greatly to the advance of botany generally.

The Conqueror's first measures were eminently gracious and conciliatory; even in rewarding his Norman followers. He, who had deprived no Englishman of anything to which he had a just claim; he probably limited his seizures to the lands and other property of those who had fallen in arms against him. He respected also the public liberties, as well as private rights; the police of the kingdom was made much more efficient, and at the same time the taxes were collected with less severity, and public order and good government were established. If the Saxons, at least some of those at Canute, been governed either more wisely and wiser or less oppressively (in all respects except that it was under a foreign domination) than it was now.

But circumstances made it allowable to this state of things. On the one side a numerous people, the old occupants of the country, exasperated by defeat, and on the watch for revenge; on the other, a handful of foreign intruders, flushed with recent victory, and feeling themselves invincible. The whole work is arranged according to the Linnaean system. From 1800 to 1809 Willdenow published at intervals descriptions with coloured plates of plants growing in the Botanic Garden at Berlin, under the title 'Hortus Berolinensis,' Berlin, folio. He has published many extemporal papers to various journals and Transactions of societies.

(Willdenow, Lehrbuch der Botanik; Biographie Medicale.)

WILLIAM I., King of England, styled THE CONQUEROR (in Latin Conqueror or Conquisitor, in French Conquereur, meaning only, in the language of the feudal system, the conqueror), was the illegitimate and only son of Robert, Duke of Normandy, surnamed Le Diable (the Devil), and was born in 1027. The Anglo Saxon story makes his mother the daughter of Fulbert le Croy, a Tanner and tanner of cloth, whom she had enamoured of as she was dancing with some of her female companions; her name, it is said, was Arlette or Harlotta, whence our English Harold. This is a very suspicious etymology. According to the contemporary historian William of Malmesbury he was the son of Hildegarde, the daughter of Hildric, and born in 1027. On the other hand, he was the son of Ethelgiva, the daughter of Ethelfred, who was married to a Roman nobleman, and the daughter of King Ethelred, and the son of Hildric, a Saxon nobleman, and of Ethelgiva, the daughter of Ethelfred, who was of Roman origin. He was the son of Ethelgiva, the daughter of Ethelfred, who was married to a Roman nobleman, and the daughter of King Ethelred, and the son of Hildric, a Saxon nobleman, and of Ethelgiva, the daughter of Ethelfred, who was of Roman origin.

The story of the early part of William's life has been given in his brief Norman anecdote (xvii. 281). He succeeded to that duchy as William II., on the death of his father in 1035. The commencement of his transactions with England and his acquisition of the crown of that country by the victory of Hastings, or rather Senlac, gained Saturday, 14th of October, 1066, have been detailed in the articles on the Conqueror.
against the city of Exeter, the head-quarters of the south-western insurrection; but with all his vigour, it was not till after a siege of eight days that the town was taken into the place, and even then he engaged that the inhabitants should not be injured either in their lives, their properties, or their municipal privileges. In this quarter of the kingdom, as yet at least, the revolt scarcely seems to have been a Saxon or national movement; it might have grown to that, but at present it was apparently little more than a resistance to some oppressive proceedings, or apprehended proceedings, of the established authorities. William was satisfied therefore with making no alteration as far as the submission of the inhabitants at the cost of some concession or compromise: it was necessary that he should not leave such a flame behind him to gather strength while he should be engaged with the more formidable rebellion in the north. That occupied him with little interruption for some time, and then for a great part of the succeeding year. At the head of it, when it had broken out, were the two earls Edwin and Morcar; they were fallen upon and compelled to make their submission; and for a time the attempt seemed to be crushed. A second rising was as speedily put down; but in the course of the succeeding summer of 1069, the three surviving sons of Harold, landed at Plymouth from Ireland, in June, with a fleet of sixty-four sail, and then, in July, Canute the son of Sweyn, king of Denmark and Norway, landed at the head of a much more formidable armament: the Irish invaders were driven back after having plundered the adjacent country; the Danes were joined by the newly quieted inhabitants of Yorkshire and Northumberland in the Tyne and opposing the invaders of the east coast, which ensued, which did not indeed last long, and in which William came off victorious, but which left that part of his kingdom literally a desolate wilderness; for, after he had subjugated the most formidable of his opponents, he was promised to be effectual in preventing a new insurrection, except actually to depopulate the country by fire and sword, and to reduce a large tract of it to the solitude and silence of death. It is affirmed that above a hundred thousand people were, by deliberate and deliberate, a terrible operation, and that for nine years thereafter not a patch of tillage was to be seen between York and Durham; nor were the ruins of the buildings that had been thrown down in the reckless devastation cleared away for more that a century.

From this time William ruled his kingdom like a true conqueror. The natives of the country were rapidly deprived of everything; and reduced to a state of complete slavery. Offices both in the church and the state, from the highest to the lowest, were usurped by the Norman gentry, and, with the exception, filled with Normans and other foreigners. On any pretence or no pretence at all, by confiscations and unjust decrees, by force or by fraud, nearly every Englishman was in a short time made a serf, and reduced to the smallest imposts. Fortresses were erected and garrisoned in all the considerable towns to overawe the inhabitants. In short the country was reduced to a vast encampment, in which the only freedom, public or private, that was left was the right of a small number of insolent masters to tyrannize at will over a multitude of toiling and helpless bondsmen.

All this however, and the deluge of blood in which the northern rebellion had been quenched, had the full effect that it was darkened the right banner of the Conqueror. He was put down a band of outlaws, who, headed by the trepied and the outlaw, was composed of the island of Ely; and they were routed out in the course of the year 1071. In 1072 the Conqueror, all England being reduced to submission, found himself at liberty to lead a great army across the northern border to chastise the Scottish king Malcolm Canmore, who, besides having received and protected Edgar Atheling, whose brother he had murdered a day before, immediately after the suppression of the Northumbrian insurrection, made an inroad into the western parts of York and Durham, and spread almost as much devastation in that quarter as the vengeance of the English king had done along the eastern coast. As William advanced, the inhabitants of the land were fled before him, but, setting fire to their farm-houses and villages, and carrying away with them everything of value which the flames did not consume, left the land a bare and silent desert. He continued his relentless march southward, and there he met the army of Malcolm at a single engagement, the following year William sent an army into Scotland under the command of his son Robert; but after advancing only a few miles (to a place which Simeon of Durham calls Egisfret), it returned without having effected anything. In the following year William was killed in the Tyne, which were ejected on the Tyne, with the view of checking these Scottish inroads.

Meanwhile, in 1075, during another visit to William to his kingdom, he was attacked by a number of Anglo-Norman barons, with Roger, the son of William Fitz-Osbern, and successor in the earldom of Hereford, at their head, offended, as they professed, at his generally haughty bearing and oppressive government, but chiefly moved, it seems, by jealousy of his ambition. He was met, taken to himself in the fruits of their common conquest, had entered into a confederacy to drive him from the throne. But their conspiracy being detected, they were hurried into an armed rising before their plans were matured, and their junto was arrested by the vicars and justiciaries William de Warrenne and Richard de Bifaut, in a battle fought at a place called, by Ordeines Vitus, Padun, by which is supposed to be meant Beecum, or Bisham, in Northumbria. Upon the death of William, the Saxons, who, under the protection of Norsemen, established his dominion over that country.

The next and only other attempt which was made in William's lifetime to shake his throne, though it were at first unavailing, was also to recover the kingdom of Denmark. What the rest had done, defeated partly by his vigilance, promptitude, and energy, partly, as one would say, by his good fortune. In 1068 Canute, the son of Sveno, who had now succeeded his father as king of Denmark, put himself at the head of a great naval armament with the awed design of asserting his hereditary claim to the English crown; William immediately collected a great army to oppose him, by bringing over multitudes of mercenaries from every part of the continent, but the king never came to the armistice of the sword; the sagacious English king having posed to have employed his treasure in corrupting the forces of his enemy, as well as in hiring mercenaries for his own defence: that it as it may, one cause or another always prevented Canute from putting to sea; the wind was contrary, or he was disappointed in a supply of provisions, or some of his captains were not to be found or were not in readiness to start: at last, after he had lain for more than a year in the port of Hals体系, or Hedeby, a port in Denmark, the king of Denmark, who was not a man of much courage, the Danish king, the King of Denmark, found the ship broke out in the fleet, and the enterprise was abandoned. It was to help him to meet this danger that William revised the odious tax called the Danegeld.

William the Conqueror and his eldest son Robert, to whom he had promised after but afterwards refused to resign, his hereditary dukedom as narrated in the article Normandy. It came to a conclusion of arms, in which the father and son are said to have occasion encountered without knowing one another.
when the old king was wounded in the hand in the unnatural combat. This was while William was besieging the castle of Gerberoy, into which his son had thrown himself. There he was eventually rescued by the intervention of Queen Matilda. It was another quarrel about Normandy however with Philip I. of France, who had taken the part of Robert, that cost William his life. In the summer of 1067 a sasarem of Philip's on the constancy of his brother Godfrey, was encountered, and the latter, who was still ill at Rouen (lying-in, as Philip phrased it), infuriated the proud Norman; he swore that at his churching he would set all France in a blaze: as soon as he was able to draw breath, he collected all those who were at the city of Mante, formerly belonging to Normandy, which he took, and immediately ordered to be set on fire. This was on the 10th of August. He was enjoying the sight of the conflagration, in which many of the inhabitants perished, when his horse stumbled on some boulders, and threw him forward on the pommel of the saddle, by which he was so much injured that, being carried back to Rouen, he never again left his bed, but died there on the morning of the 9th of September following, in the fifty-eighth year of his age and the fifty-first year of his reign.

What manner of man the Conqueror was may be sufficiently gathered from this outline of his history. His character has been graphically sketched by the Saxon chronicler from personal knowledge—"as for we looked on him," said he, "and some Norman, but also an Englishman (lieg-ing his hereditary foe)," The feature that had chiefly impressed itself upon this close observer was what he calls his sternness, by which he seems to mean his unyielding bent of will and indomitable character. Three times in the course of his description he remarks this. But while he was stark beyond all measure, and very savage to those who withstood him, the honest chronicler states, on the other hand, that he was mild to good men who loved God, and that he was a very wise man, as well as very much more worthful and strong than any of his ancestors. William indeed was far from being all devil, any more than his father (Robert le Diable), whom he seems to have a good deal resembled, and who was complimented by his contemporaries as a typical man of instinct, as well as with the other expressive surname by which he is commonly remembered. With all his ferocity, William evinced throughout his life a reverence both for the ordinances and the ministers of religion; and, although he would not suffer other his tyranny and popery first within his kingdom an ecclesiastical dominion separate from and independent of that of the crown, he showed himself anxious on all occasions to maintain the respectability of the church by promoting able men to the chief places in it, as well as by his own personal exemplification of its legal rights and duties. He was eminent with the qualities, both moral and intellectual, that raise men above their fellows, is abundantly proved by what he did. Few men have projected the influence of the genius that surrounded him, and his character was the outcome of the Norman dynasty in England. In moral disposition William was passionate and ruthless; but he does not appear to have been vindictive, nor even, properly speaking, cruel or bloodthirsty, notwithstanding the destructive character of some of his military operations. There was nothing weak, nothing little about this great king. In his latter days, the chronicler intimates, he fell into the vice of avarice and greediness; but this love of money was only one of the forms assumed by his love of power. On the contrary, so utterly mystic was the whole of the forms in which the energy and ardour of his character were displayed was his passion for the chase. So much he loved the high-deer (ha ha door), naively writes the Saxon annalist, as if he had been his father. It is plain, he was not an idle man. As he frequently rode for the chase he received quite as much of his affections as his children, and somewhat more what than his subjects. He made laws, says the chronicler, that whoever should slay harm or hind, him and his kindred. As he feared and the coasts of his Angevin counties he made laws upon the assembly of the principal persons of the greater the year 1070.

The principal portion of the laws of the Conqueror that has come down to us consists of a capitation which is supposed to have been drawn up and agreed upon by the principal persons of the greater the year 1070. This is the most part a selection of the laws previously in force in the Saxon times, according to their last general revision by Ceante the Great. It exists both in Latin and in Romance, or old French, text. The first text is that preserved in the history attributed to Inglaphus, has usually been reckoned the original; but Sir Francis Palgrave, who has printed both versions from better manuscripts than had been before employed, in his 'Rise and Progress of the English Con- queror, William I.,' has advanced some reasons for believing that these laws of the Conqueror were most probably originally written in Latin, which was the language in which legal documents were common, and that they were subsequently translated for an account of the memorable survey of the kingdom completed by order of William in 1066, see the article DOMESTIC-BORROW (II.)

The wife of William the Conqueror was Matilda, daughter of Baldwin V., Earl of Flanders, named the Gode. He married her before he acquired the crown of England, and she died 2nd November, 1083. Their children were Robert, whom his father called Gambart (Rondelis, and Courtouche (Shortsallah, who died a prisoner in the castle of Cardiff in 1194; Richard, who was said to have lived to the age of eighty; William, whose death is not chronicled, William, who was succeeded on the English throne; Henry, who succeeded William; Cecilia, who became abbess of the monastery of the Holy Trinity at Caen, and died there 1210, who married, first, the count of Bremgarten and Richmond, but died without issue; Adela, who died young before the Conquest; Adela, who married Stephen, Earl of Blois, by whom she became the mother of Stephen, king of England, and who afterwards took the veil, and died in the Norman convent at Mortain, 1137; Gundred, who married William de Warren, Earl of Surrey, and died in childbirth at Castlemere in Norfolk. 27th May, 1065; and Agatha, who was converted to Al- phonsus, king of Leon and Castile, and died before her marriage. Their eldest daughter was Maud, daughter of Ingelric, a Saxon nobleman, who afterwards married Ranulph de Peveril.

WILLIAM II., King of England, named by his French and Norman contemporaries Le Roux, and by the English TG, the Red-Haired, or the Red-haired, is the second of the three surviving sons of William the Conqueror, and the last of the Norman kings. This was the case after the death of the celebrated Lanfranc, whom, in 1083, his father had called from his retirement at Bec to preside over the newly-founded monastery of St. Stephen, at Caen, and whom he afterwards, in 1070, made archbishop of Canterbury. Lanfranc was the man he had chosen not only as an instructor in learning and piety, but in the art of war, and it was from Lanfranc that Rufus received his knightly character. He appears to have been of a bold and forceful character. His father, who saw himself in his own of his own character than in his eldest son, the thoughtless and indolent Robert. A few days before his death, the Conqueror, having assembled around him his three sons, took those of his prelates and barons who were with him, and called them to his bedside. He said that he never thought one day of his departure, that no matter how he might fall to William; and he advised that prince, who was present (Robert was not), to repair immediately to England, giving him at the same time a recommendation letter to the king of England, and the next day he died. His body was embalmed, and was carried to the castle of Dover, Pevensy, and Hastings, on which matters, see the brothers of his father; he then hastened to Winchester, where he also was buried in the church of the royal treasury, William
de Pont de l'Arche, to give him his keys; and finally he presented himself before Lanfranc, to whom he had already forwarded his father's letter by a confidential messenger. Lanfranc a few days after assembled a council of the prelates and barons, and, by one of his propositions, that William should be declared king; and he was accordingly crowned by the archbishop at Westminster, on Sunday the 28th of September, 1087. The commencement of his reign is dated from that day.

The last claim to the throne of the Red King had to address himself, was to defend the throne which he had thus mounted against his elder brother, Robert, who at the time of his father's death had been living in exile and power. But the death of the last remaining of the house of Blois, which was in the dominion of the king of France, soon made his appearance at Normandy, and so strong a claim was made on the throne of the Red King as to be acknowledged as duke of Normandy. It may be doubted whether he would not have been satisfied with this ancestral inheritance if he had been left to himself; but this, in the circumstances, could hardly be. His chief instigator was Odo, the bishop of Bayeux, who, in the latter years of the preceding reign, had fallen under the displeasure of his half-brother the Conqueror, and was now eager to avenge himself by the dethronement of Rufus. Many others of the English barons and Normans of the house of Normandy, in both countries were strongly averse to their separation, as involving the inconveniences and risks of a divided allegiance. Odo is said to have arranged his plans with his friends at the festival of Easter, 1088, which was kept by William of Winchester and Robert at Forest of Seine, which was one of the last meetings of Pevensey and Rochester, with Odo in the interior, and Eustace, earl of Boulogne, in the latter, were both compelled to surrender; and the rebels, after some further ineffectual resistance, soon everywhere threw down their arms. The union of the two kingdoms, both in the mind and in the heart of the people, was speedily followed by a revolt of many of the Norman barons against Duke Robert, who, with difficulty was able to maintain his ground, even with the assistance of his brother Henry, to whom in his necessity he had recourse. This, however, did not avail to the recovery of the loss he had sustained in England. [Henry I., vol. xii., p. 118.] After this civil war had gone on for some time, and Normandy had been reduced to a state of almost complete anarchy, William landed in that country at the head of an army, in January, 1089, and joined his brother, making a revolution in England speedily followed by a revolt of many of the Norman barons against Duke Robert, who, with difficulty was able to maintain his ground, even with the assistance of his brother Henry, to whom in his necessity he had recourse. This, however, did not avail to the recovery of the loss he had sustained in England. This was the moment when he could be pressed; and he soon managed to raise the required sum, not, as an old writer expresses it, by merely fleecing his poor subjects, but rather, as it were, by baying off their skins. The people of Normandy in general submitted quietly enough to this transfer of power, and the new king, in Normandy, was received as a new lord; but the Manceaux, or inhabitants of the district of Maine, Robert's right to which he disputed, rallied around his rival claimant, Helie de la Fleche, and attempted to set William's authority at defiance. This opened the way for the Conqueror to land his forces on the Continent in 1100; he was hunting in the New Forest when a messenger arrived with the news that Helie had surprised the town of Mans, and was besieging the Nor- man garrison in the ruined castle of the latter. Rufus immediately set out, and after a battle fought near the sea-port of Dorset, where the Normans were defeated, he left the castle in ruins, and, retreating into France, he was defeated by the duke of Normandy, and forced to make a treaty with him. The treaty was signed at the castle of Aumale, in the presence of the king and the duke, and was ratified by the king and the duke, and was ratified by the king's son, William the Steward, who was then a young prince, and by the duke's son, Henry, who was then a young prince, and by the duke's son, Henry, who was then a young prince, and by the duke's son, Henry, who was then a young prince, and by the duke's son, Henry, who was then a young prince.
have not even assigned to him any natural children, notwithstanding all the licentiousness that is attributed to him in his private affairs. The chroniclers, who were all at that time sinners, have drawn his character in the darkest colours, and it may be presumed that he is indebted for some portion of the infamy and malversation they have heaped upon him to the manner in which he treated the church, of which he was throughout his reign the systematic oppressor and despoiler. His conduct in regard to that matter is detailed in the article Anksilm (ii. 57). At the same time it is sufficiently clear that neither as a man nor as a king did he much care for restraints of any kind more than those of royal dignity and the rights of property, and the desire of undisputed sceptre, and in the main regardless of everything except his own interests and passions. He was also however not without some of the better points of his father's character, sharing largely not only in his courage and energy, but likewise in his political talent. Rufus, with all his ruffiansm, too, had a taste for some of the true splendidours of civilization, and showed that he was not altogether sunk in sensuality by devoting part of his wealth to architecture, the only kind of fine arts which a king could in his day do much to encourage. Besides other erections of less magnificence, he was the builder of the first Westminster Hall. The commissioners of the Fine Arts, in their Report, dated 24th March, 1843, state that 'they have reason to believe that three-fourths of the space occupied by William Rufus occupied the same area as the present building.'

WILLIAM (HENRY) IV., king of England, was the third son of George III., and was born at Buckingham House, on 21st of August, 1765. He was married, with his elder brothers, the Prince of Wales and Prince Frederick (afterwards duke of York), under the care of Dr. Majendie, till the year 1771, when a separate establishment was formed for the two elder princes, and Prince William was sent to generalterms, with his younger brother Edward (afterwards duke of Kent), under the superintendence of Colonel Bude, a native of Switzerland, who afterwards became private secretary to the duke of York. It having been determined that he should enter the navy, he was, on the 14th of March, 1779, rated as master and commander of His Royal Highness's frigate, of 86 guns, then bearing the flag of Rear-Admiral Digby at Spithead. The Prince George soon after joined the Channel fleet, under the command of Sir Charles Hardy, and in the end of the year sailed as one of the squadron sent out from Rochefort to Gibraltar as a supple-
ing for the garrison. On the passage out they fell in, on the 8th of January, 1780, with a Spanish fleet of store-
ships, under the convoy of seven men-of-war, and took three of them; twenty in number, with the largest of the war, the Guipusecano, of 94 guns. Rodriguez, the Prince William, 'in respect to his royal highness, in whose presence she had the honour to be taken.' In this first affair however in which his royal highness met the enemy there was no actual collision. But eight days after, on the 23rd of April, fourteen ships of the line, commanded by Don Juan de Langara, was encountered off Cadiz, and a sharp though short engagement ensued, which ended in the capture of several of the enemy's ships and the destruction or dispersion of the rest. Rodney, having then proceeded to the Bay of Gibraltar and thrown in his supplies to the garrison, lay there for about three weeks, during which time his royal highness often visited the rock. The Prince George returned in the division under the command of Admiral Digby, which anchored before the port, and on the passage fell in with a French convoy bound for the Mauritius, of which he captured three store-ships and a man-of-war; and his royal highness found himself again in England by the beginning of May.

Having made two, or three short cruises in the Prince George, he then went out a second time to Gib-

raltar in that ship in the spring of 1781, in the fleet commanded by Admiral Darby. After this Admiral Digby, who was now promoted to the rank of admiral and transferred from the Mauritius to New York in America, which he reached on the 24th of August. While his royal highness remained here, which he did throughout the winter, lodging in the town, it appears that a plan was arranged by some of the revolu-
tionary parliament, with the intention of getting possession of his person; but the attempt was never actually made. In the autumn of 1782 he was, at his own request, transferred on board the Warwick, 60 guns, commanded by Captain Elphinstone, afterwards

Lord Keith; from which however he was soon after, by the king's orders, removed to the Barfleur, commanded by Sir Stanhope. He sailed with this ship, then lying off Staten Island, that he made his first acquaintance with Nelson, at the time commanding the Albermarle frigate, whose fast friend he ever afterwards continued. In the early part of 1788 Sir Samuel, now Lord Hood, arrived with his fleet at Port Royal, Jamaica; and his royal highness remained here and at the Havana, to which he proceeded in the Fortunee frigate on the sailing of Lord Hood for England, till midsummer, when he returned home in the Fortunee, in which he reached Spithead on the 20th of June, having seen the capture of the French man-of-war, on which he set out 31st July, 1783, attended by General Bude and Captain Merrick, and in the course of which after being joined at Hanover by his brother Frederick, the styled Bishop of Cambridge, he visited Berlin, where two young English princes saw a great deal of France, the Great, Luneburg, where they spent a winter, Gtin-

gen, Hesse-Cassel, &c., after which Prince William pro-
cceeded alone through Switzerland to Savoy and Piedm-
ent, where he visited Prussia, and returned to Italy, where he spent the winter. Having come back to England in the spring of 1785, he was, after the usual examination, passed as a lieutenant on the 17th of June, and appointed first lieutenant of the Hebe frigate, in which he soon after sailed for a voyage to the South Sea, and of the 17th of July, 1783, he was, as a reward of his royal highness, having previously risen to be second lie-
tenant of the Hebe, was removed to the Pegasus, and re-
ceived his commission as captain. In this ship he soon after sailed for Newfoundland, thence to Halifax in Nova Scotia, and then to Antigua, to which place Lord Nelson commanding on the Leeward Islands station in June, 1787, he was ordered to Jamaica, from which how-
ever he soon after took upon him to return without instruc-
tions to Lisbon. He was irregularly retained at Port-

quebec, but, after staying there a short time, he ventured again to take his own course, and set sail for England. He arrived at Cork in December, but was immediately ordered to repair with his ship to Plymouh; and when he got there, he was appointed on board the Prince of

herself, with his brother the Prince of Wales, from his first entrance upon public life, to the party of the Whig opposition; but he also followed the prince in giving his support to Pitt after the commencement of the war with France in 1718. On the return of Pitt to power however, after the ejection of the Addington administration, in 1804, he again joined the opposition with the prince and the Duke of Sussex; and after Pitt's death he gave a zealous support to the new ministry of Fox and Grenville on all subjects except only the abolition of the slave-trade, which he opposed successfully; and the consequence of this was the conviction of the Sicilian rebels, and a vote of censure against Sir William Amory, with the avowed design of ascertaining by a new election the sense of the people on the measure which had been thus for the present defeated or abandoned.

The new parliament assembled on the 14th of June, and the general appeal to the people was made in the same way as shown by the second reading of a second Reform Bill being carried in the House of Commons on the 4th of July by a majority of 367 to 251. It was not till the 19th of September that the House came to a vote on the third reading of the measure, and the opposition was defeated by a majority of 236. The measure however was defeated in the Upper House on the 3rd of October, by the second reading being negatived by a majority of 199 to 156. On the 20th parliament was prorogued.

A new session commenced on the 6th of December; and on the 12th Lord John Russell introduced the third Reform Bill, the second reading of which was carried on the 17th by a majority of 324 against 162. If the friends of the measure had not met with one more numerical and political success, that its opponents were growing weary of the contest, and were hopeless of ultimately averting it. On the third reading nevertheless, the vote upon which did not take place till the 19th of March, 1832, the opposition mustered again their former forces, but the motion was defeated by a majority of 355. This time the measure was also so far successful in the Lords that the second reading was carried in that House, on the 13th of April, by a majority of 194 against 175. But on the 7th of May ministers were defeated by a majority of 111, and by a majority of 122 against it. It received the royal assent, and became law, three days after.

The bringing about of this change thus occupied, almost to the exclusion of all other measures or questions, the first two years of the reign of William IV. The action of the ministry was directed towards the accomplishment of the great project of extending the territory of the country in Europe. The碳酸一钠的高性手段, from which the memorable movements on the continent of Europe with which the accession of a new king in England changed to be coincident. The publication of the ordinances of Charles X. was followed by the new machinery of government, set up after King William's accession: then rapidly followed the revolution of the Three Days in Paris, the dethronement of Charles, the transference of the French crown to the duke of Orleans, and the close of another month, the publication of the order of the minister in Brussels, which terminated in the separation of Holland and Belgium. In England the first symptom of wide-spread popular uneasiness, dissatisfaction, and tendency to outbreak was the commencement of the Exchequer fire which alarmed the country in the months of September and October. The new parliament, elected since the accession of the new king, met on the 26th of October. On the 7th of November immense excitement was occasioned in the metropolis and elsewhere by the report of the resolution of the House of Commons, which was ordered to be drawn up by the responsible advisers of his majesty that he did not venture with safety to his person to dine on that evening with the lord mayor and corporation of the city of London in Guildhall. This resolution was from the orders of the Duke of Wellington, Sir Robert Peel, and the other ministers, on Sir Henry Parnell carrying the motion in the House of Commons for referring the settlement of the civil list to a select committee, by a majority of 324 against 162. His majesty's administration was in office under the banner of parliamentary reform. Meanwhile commotion and confusion were spreading on the Continent. Besides some minor eruptions of the same kind, the insurrection in Poland broke out— an unhappy attempt, which was entirely unsuccessful.

On the 1st of March, 1831, Lord John Russell, as the organ of the cabinet, and, as was universally believed, with the concurrence of his majesty, moved for the first Reform Bill. On the 22nd of the same month the second reading was car-
defeated on the address by 309 against 302. They main-
tained the struggle for six weeks longer; but at last, up
upon Lord Russell's motion against them, on the Irish
titch question (the famous appropriation clause) by a majority of 295 to 258, on the 7th of April, they
resigned the next day. The king, understood to be
now thoroughly hostile to his old friends, in vain attempted
a further resistance; by the 18th the Reform party were
again in power, with Lord Melbourne as premier. But to
Lord Durham, Lord Stanley, Sir James Graham, Lord
Ripon, the duke of Richmond, Earl Grey, and Earl Spencer,
who, having all belonged to the original Reform
party, had the space of time to hold office, died Lord
Brougham. Lord Melbourne's administration lasted for
the remainder of the reign. Its most important measures
were the several municipal reform acts. [Borough.] Williams,
1 died and, after a short illness, on the
morning of the 20th of June, 1867. He was succeeded by
Queen Victoria.

WILLIAM of Wykeham. [Wykeham, William of.] WILLIAM of NEWBURY (in Latin, Gulielmus Nebrigensis) is said to have been born at Birdlington, in 1164, and that his life had been passed on
whence he sometimes designs himself Pavus, or Petit. His
common name he derived from the monastery of New-
bury in Yorkshire, of which he was a member. Nothing
more is known of his personal history, except that he is
described as a man of extreme disapprobation of the
ric of St. Asaph on the death of Guargr of Monmouth in
1165, and that he appears to have been alive in 1220. He
is known as the author of a Chronicle of England, which
came to him in the year 1191, and is written in Latin
than was then common. It was first printed in
1260. at Antwerp in 1297, under the title of 'Gulielmi
Nebrigensis Rerum Anglicarum Libri V.' The subsequent
ditions are, 'Gulielmus Nebrigensis de Rebus Anglicis,
eum nota. pro parte, &o., Pars I; 1190, and 'Gulielmus
Nebrigensis Historiae Ave Chronica Rerum Anglicarum,
Libris quinque, a codice MS. pervetusco in Bibliotheca
Thomae Sebright, Bar.; Studio atque Industria Th. Hearns,
qui e prater Joan. Picardi annotatione, &c. ...
was adjut. 3 vol. to., Oxon. 1719. William of
Newbury is a keen castigator of the British legends
tailed by Geoffrey of Monmouth.

WILLIAMS, JOHN, lord keeper of the great seal of
England, and afterwards archbishop of York, was the son of
the Earl of Pembroke, and was educated in England and
in Wales, where he was born on the 25th March, 1592.
He received his earliest education at the public school at
Rutland, and entered a student of St. John's, Cambridge,
under the vacations of 1598. He was afterwards connected
with a great Welsh family, and was early looked upon as one likely
to be of distinction in the principality. 'One thing,' says
his entertaining biographer, Hacket, 'put him to the blush
and the little shame, that such as had bigger spleens would
laugh at him for his Welsh tongue. For those who knew
him at his admission into St. John's Society, would often
say that he brought more Latin and Greek than good
English with him. This also plucked advantage after it:
for it made him a very retired student, by shunning com-
pany and conversation, as far as he could, and the
rudeness of his native dialect.' His studious retirement
does not seem to have been of long duration. He
was largely supplied with money, and distinguished himself at
college by a gay life and profuse expenditure. 'From a
year old,' says the historian, 'he began to learn to
hold money, for he did not only lay out, but scatter,
nspending all that he had, and somewhat for which he could
be trusted. Yet he was a diligent and ardent student.
1335 and between the years 1538 and 1539, he
acquired a facility in many of the principal
languages and applying terms of art. When he afterwards
sat on the bench of the Court of Chancery, and lawyers
who professed a contempt for his legal acquire-
ments, and who were content to puzzle him with pedantic
technicalities, he turned the tables by the application of
upon his old studies in scho-

dom. He read the best, he heard the best, he conferred
with the best, exercised, committed to memory; despised
that which he never did so much in this unwearied industry as
himself desired, he did far more than all that did highly value
him could expect. All perceived that a fellowship was a great deal too little for his head and heart. As he went on,
that went the pace would quickly go farther than St. John's
walks.' In 1625 he took the degree of master of arts.
He entered into holy orders in 1609, accepting a small
living in Norfolk, and in 1611 he was instituted to the rectory
of下一代. [Borough.] When he entered
office, he added his name to the charter of incorporation
of the foundation of his subsequent greatness was laid by his
being chosen chaplain to the lord chancellor Egremont. He
had been able to secure the favourable notice of King
James by his conduct in relation to a slight dispute be-
tween his majesty and the university of Oxford, and
when he had formed his new office, 'a nest for an eagle,' as Hacket calls it, gave
him such access to the royal person as enabled him to
profit by the favourable impression. 'The chaplain
understood the soil upon which he had set his foot; that
as rich and fertile, able to grow good tobacco, to
yield a crop after the dimensions of his desires.' Fortunately
for himself, he refused the offer of remaining in his chaplany
under Bacon; perhaps his worldly shrewdness taught him
that the soil was undermined beneath. He
had been chosen chaplain in ordinary to the king, in 1619, he preached before James at Theobald,
and the sermon was printed by command of his master.
who soon afterwards gave him the rich deanery of
Newbury. But Williams could only look upon that
advancement as a step towards the desirous object of
being named to the archbishopric of Canterbury, and desiring to befriend Williams, recommended
him to seek the patronage of Buckingham. He
developed the friendly hint, and acted the part of apostle in reces-
in the conscience of the favourite's Roman Catholic
belief. On the 11th of April, 1621, he was named to the
church of Canterbury. Of parts and talents, a good example of
the elements of the doctrinal belief of the Church of England,
which he drew up on this occasion, twenty copies were
printed by order of the king. It was by the advice of Wi-
lliams that Buckingham adopted the bold project of ser-
vice, or the procuring for himself and his victims such
objects as the foundation of this church, of his
voters, and the introduction of the English prelates
into the counsels of the sovereign. The project was more successful than ordinary human foresight
could have anticipated, and though it was an unpopular
measure to renew the practice of committing the great
to the hands of an ecclesiastic, the favourite's gratitude
overcame its caution, and the order of the
was at his command, a crowd of court spies, whose
information he turned to his own advantage. When the Mar-
quis Inoico, the Spanish ambassador, had succeeded in
injuring James into the belief that he was a prisoner in
the hands of Buckingham, Williams was able to inform him
of his extensive influence, and to suggest a remedy. Buckingham however appears to have
soon entertained a fear that the lord keeper was seeking
too great a share of independent power, and his run was
received on. Laud, whom he was the first to
make a candidate, he believed, was not percet that the keeper was sinking, 'he shunned him,' says
Hacket, 'as the old Romains, in their superstitio, walked
from that soil which was blasted with thunder.' Laud
was a tall, tall man, and with a facility in which the
miss is father to the thought. In the meantime
Buckingham himself sunk in the favour of James, and
Williams remained lord keeper till the accession of Charles
when, in October, 1625, he was deprived of his
bishops to the minor orders and of his
the House of Lords, but he was not a man to be intimidated.
He retained his place on the bench of bishops, and, as far
as his High Church principles would permit, supported the
popular cause, and exerted himself in promoting the Pei-
tion of Right. His relentless rival Laud raised against him, in the Star Chamber, a charge of betraying the king's secrets, contrary to his oath as a privy councillor. He was convicted of subornation of perjury in defending himself from this charge, fined 10,000l., suspended from his offices, and fined fashion and a withdrawal from the House of Commons, which subsequently dissolved. He went to Germany and then to Austria, where he was sent to prison. Since the meeting of the Long Parliament in 1640, he was re-elected, and resumed his seat in the House of Lords. A revolution had now taken place in the court; he was received into favour, and in the following year translated to the archbishopric of York, Dr. O. became bishop of that see in 1649. He was sent to Scotland in 1650 to arrange peace, and was afterward sent to Wales, and held out Conway Castle for the king. He died on 25th March, 1650. Clarendon charges Williams with being vain, peridious, and revengeful. Woulton and others accuse him of having been a peremptory and injudicious magistrate. The official history of the time is wanting. But he was a most independent judge, and his employers engaged to confine him to the commercial department. Young Williams soon displayed an inclination for the workshop rather than the counter, and his master, Mr. Tonkin, found it to his interest to employ him in executing orders which required peculiar delicacy and skill. He would also frequently volunteer his services for bellying down similar out-door employments. While thus employed, Williams became connected with companions whose irreligious habits threatened to exert a most fatal influence upon his character; but on a Sunday evening early in 1641, while walking in the street for some dissipated companions with whom he intended to spend the evening at a tavern, he was recognised and accosted by Mrs. Tonkin, the wife of his employer, who was then on her way to the Tabernacle, Moorfields. She accosted him and engaged in conversation with him, and one of the religious community at the Tabernacle, joined a class of young men formed for the purpose of mutual improvement, and became an active Sunday-school teacher. Missionary operations were then exciting the lively interest of the Tabernacle congregation. Matthew Wilks was exerting himself to extend a sense of their importance; and at one of the numerous meetings held with this view, Williams became impressed with a strong desire to devote his talents to the service of the cause of Christianity, and in some islands the cruel rites of idolatry had been entirely abandoned. So far from the difficulties of the missionaries being removed by this happy change in their circumstances, they were rather increased by their success; the number of agents in the field being totally insufficient to supply the necessities of those people who were already emerging from barbarism. Williams, having been engaged in the work of labouring with very little success; but before the time when Williams offered himself to the Society, many of the natives had embraced Christianity, and in some islands the cruel rites of idolatry had been entirely abandoned. So far from the difficulties of the missionaries being removed by this happy change in their circumstances, they were rather increased by their success; the number of agents in the field being totally insufficient to supply the necessities of those people who were already emerging from barbarism. Williams offered himself to the Society, many of the natives had embraced Christianity, and in some islands the cruel rites of idolatry had been entirely abandoned. tion to the great design of teaching the gospel, to introduce among the heathen the arts of civilized society. In October, 1816, Williams married Miss Mary Chaufer, who proved an invaluable coadjutor in his future labours; and on the 16th of November following Mr. and Mrs. Williams, in company with several other missionaries, embarked for Sydney, whence after a short stay they proceeded, after calling at New Zealand, to Eimeo, one of the Society Islands, which they reached exactly twelve months after leaving London. Here they remained for some months, Mr. Williams continuing the mission on the island, while his夫人 and the missionaries removed to Hoshine, another island of the same group, where they were very gladly received by the natives. The fame of their arrival brought visitors from the surrounding islands, and the urgent solicitation of the king of Raiaetea (the Ulte of Captain Cook), induced Messrs. Williams and Threlkeld to remove to that island, which is the largest and most central of the Society group. Its population was at that time about 1300, but its political influence was far greater than that of the other islands, and its principal chiefs received divine honours, as well as civil allegiance and tribute, from the neighbouring isles. 'From time immemorial,' observes Mr. Prout, 'this island had been the focus and source of the abominable idolatries which prevailed, demonizing the inhabitants of its own and the surrounding shores. Here were to be found the types of the manifold usages, even the most degrading and cruel, which had become the customs of the race; here were the archives of their religious legislation, and the index to the sacrilegious actions and altars of the surrounding sea.' Among the inhabitants of this island, Williams found them extremely debased, and their idleness apparently inveterate. They were also so scattered over the island as to render collective instruction almost impossible. It was indeed evident that their habits must be entirely remodelled before the natives could hope to become at all useful to society. Without neglecting the principal object of his mission, Williams induced the Raiaeteans to collect themselves to one spot, and to build habitations for themselves, as well as a church and a school. Having thus erected a comfortable house in the English style, presenting a model to which the natives were encouraged to look both in its structure and conveniences, and in the furniture with which it was adorned; almost everything being done by their own hands. The natives were thus taught not only to appreciate the comforts of civilized life, but to obtain them for themselves, by constructing houses with two or more apartments, with wooden floors, framed wainscoted with coral lime, thatched roofs, well-stocked gardens, and lawns, and bedsteads covered with the finest structural leguminous leaves and hangings. They were also instructed in boat-building, and their diligence and ingenuity were excited by judicious rewards in the form of nails, lunes, and other useful articles which the missionaries procured from England. Procured the spirit of imitating the visible necessities, and to put them in the right way for supplying them, the missionaries were at length gratified by a request to attend a meeting convened by the natives for the purpose of improving their physical and moral condition. This is not the place to rebut the charges which have been brought against the missionaries, of substituting a despotism of which they were the heads for that previously existing under the chiefs. The most weighty and circumstantial statements contained in such works as those mentioned at the end of this article; statements which bear the most undeniable internal evidence of sincerity and truth, and which have been corroborated by several persons whose testimony stands clear of the slightest suspicion of partiality. In May, 1820, upon the occasion of the opening of a new chapel at Raiaetea, at which more than 2400 persons were present, a complete code of laws was established by the votes of the people, and it differed from those previously introduced in other islands of the South Seas in the important point of the introduction of Christian principles. It was properly administered by a body of twelve elders, which had been formed by the natives, under the immediate superintendence of their instructors. Being desirous of extending to others the benefits which they enjoyed themselves, the Raiaeteans (as they were now called) were supported by liberal donations of such articles as they had learned to prepare for sale; and Mr. Williams laid the foundation of future commercial wealth by teaching the people to cultivate tobacco and the sugarcane, and to prepare sugar for the market. With this view he constructed a sugar-mill, the rollers of which were turned in a lathe formed by his own hand. The benevolence which prompted Williams to such exertions could not rest content within the narrow limits of the island. He remained long in Tahiti, and embarked in occasional boat-voyages. The intelligence received from time to time from other islands gave him a strong desire to extend the peaceful conquest in which he had so distinguished a part, and he perceived that nothing was more suitable than the planting of missions for the civil and religious elevation of the islanders. Although not seconded in these views by the directors of the Society, he was so fully convinced of the importance of the scheme that he determined to bring it effectually into execution, rather than abandon his project. He therefore visited Sydney about the commencement of 1822, and purchased a schooner of from eighty to ninety tons, called the Endeavour, in the hope that the Society would, upon full examination, support his views; and the necessary purchase of the vessel. He also made arrangements for promoting the rising commerce of the islands, and returned with several cows, calves, and sheep, presented by Sir Thomas Brisbane, governor of New South Wales. Having the use of some islands, Williams sailed from Raiaetea in the Endeavour, for the Herno Islands, calling at the mission-station of Aitutaki, where he endeavoured to carry into effect a long-cherished scheme for the discovery of the island of Raobog. He sailed from Aitutaki in the 5th of August, 1823, the result of the short voyage, and cleared up the report of a few of its natives upon other islands. Failing in his first attempt, he visited Mangai, and some other islands, but so length, as is described in the sixth chapter of his Missionary Deserts, by so much the better to discover the secret of the Herno, Leaving a native teacher there, with a promise of sending further assistance, the Endeavour shortly returned to Raiaetea, whence she soon sailed upon another expedition to Resutto and Rukatou. As the vessel was on such a purpose, the indefatigable missionary was preparing for a more distant expedition to the navigators and other islands, when his projects were suddenly checked, and he himself was involved in most painful embarrassments, by the circumstances of the employment in which he had procured the enactment of fiscal regulations by the governor of New South Wales, which greatly impeded the development of trade from the South Sea Islands, and rendered the retention of the Endeavour impossible. Deprived of his native friends (for the society had disapproved of the steps he had taken with regard to the ship, they having a very commendable jealousy of anything that could, even in appearance, tend to undermine the prosaic condition of the natives), he was thus compelled to send the ship, laden with the most marketable produce that he could collect, to Sydney, with orders for the sale of both ship and cargo. Grieved as he felt this disappointment, he did not escape with as much inconvenience in absence for a time, while he devoted his energies to Raiaetea, where
it was found necessary, from the frequency of destructive storms, to remove the settlement to the opposite side of the island.

In the autumn of 1825 Rarotonga and other of the Hervey islands were revisited by the Rev. Mr. Bourne, one of Williams's fellow-labourers, in the 'Hawea,' a vessel chartered for the purpose by the Society. In December of the same year Williams was joined by Mr. and Mrs. Pechell, who had appointed to go to Raratonga, in which he returned to Raratonga, but remained with him for some months at Raiaeta, before proceeding to their destination. In April, 1827, they obtained a passage to Raratonga, accompanied by Mr. and Mrs. Williams, who contemplated staying a few months there, and then returning to their vessel, 'Cordage,' which had been chartered in Rarotonga, but it was not until the following March that the vessel was in sight north of the island. Here Williams was informed that all efforts had been made to reduce the number of labourers on the South Sea Islands, and to reduce the voyage to a written form and a grammatical system. When at length prepared to return to Raratonga, he waited month after month for an opportunity of doing so, and, when long expected to be of no hope of a vessel, all hope within sight, he determined on it. In the meantime, however, having limited his knowledge of naval architecture, the total absence of assistance beyond what the natives could render, and the lack of iron and tools, of which he had a very small stock for the public, plans of the vessel were made, and the undertaking was the construction of a pair of smith's bellows, to obtain leather for which three of the four goats on the island were killed. It must have proved extremely mortifying to find that when the machine was completed it did not act properly, owing to a little oversight in the construction, but the perplexity was utterly terminated by the entire destruction of everything but the boards by rats, which surrounded at Raratonga. Undismayed by this misfortune, Williams contrived a blowing-machine, which was fully sufficient for the construction of the ship, and the plans and instructions and explanations as to the accomplishment of an important and useful object by means less complex than the machinery of civilized countries. Having to work in the trees, which were split by wedges, and having to steam-hammers, the native bellows, and splitting curved trunks. Cordage was manufactured of the bark of the Hibiscus; sails were made of native matting; and for oars were substituted cocoa-nut husk, banana stalks, and even the ship itself, which was used as a mission, was of iron-wood, or iron-wood, by means of a lathe constructed for the purpose, and the pipes of the rudder were made from a piece of a pickaxe, a cooper's adze, and a large hoe. By such contrivances, in the short space of fifteen weeks, was completed a sea-worthy vessel about sixty feet long and eighteen wide. Supplied with anchors of wood and stone, and with a crew consisting only of natives, Williams first tried his vessel, which he styled the 'Messenger of Peace,' in a voyage of about 170 miles to Aitutaki, which was attended with all kinds of difficulties, as well as with the breaking of the foremost through the inexperience of the native crew; and after a few days the vessel returned to Raratonga with a valuable cargo of pigs, cocoa-nuts, and coconuts. Shortly afterwards Mr. and Mrs. Buzacott arrived at Raratonga with a vessel, 'Cordage,' which enabled Mr. Williams to strengthen his ship before sailing for Tahiti, a distance of 80 miles, which he accomplished in safety. Being now fully determined to undertake his proposed voyage, he asked Williams if he could supply all the preparation for it. He however returned to Raiaeta, and was actively engaged in that and neighbouring islands for a considerable time before the great expedition could be commenced. On the 28th of May, 1830, the 'Messenger of Peace' left Raratonga on this important voyage, for the circumstances of which we must refer to the interesting narrative of the mission.
to carry out his long cherished design of visiting the island yet further westward, where as yet nothing had been done for the instruction of the savages. The expedition was proceeding successfully, and had reached the New Hebrides, when, on the 20th of November, 1859, a party from the ship landed at Dillon's Bay, in the island of Erromanga, where the natives, irritated, is reason to believe, by the barbarities perpetrated by the crew of a vessel that had previously visited the island, attacked them, and murdered Mr. Williams, then in the forty-fourth year of his age. Mr. Harris, who had been living for some time a missionary to the Marquesas. The intelligence of the melancholy event produced the most intense excitement both in the numerous islands where the apostolic labours of the late Mr. Harris had been performed, in his native Oxford, and the universal esteem which his character had obtained called forth the warmest expressions of respect and regret. Such remains of the body of Williams as could be subsequently procured (the greater portion having been devoured by the cannibals of Erromanga) were interred at Apia, in the island of Upolu. It is most gratifying to know that the benevolent work to which Williams devoted his life has not been checked by his untimely end, but that even upon the very island on which he fell the truths of Christianity have taken deep root with gladness.

Of the character of Williams it is unnecessary to attempt to form an estimate in this brief notice. To comprehend his self-denying zeal, his unconquerable perseverance in the pursuit of the philanthropic objects of his ministry, the fidelity of his holy trust, his great love of instruction, and the benevolence which marked his public and private actions, it is necessary to peruse the circumstantial narrative of his 'Missionary Enterprises,' a book replete with interest even to those who do not duly appreciate the multitude of great and noble works which have been the means of advancing, and so by his subtility, dexterity, and ingenuity, he got now to be a principal secretary, absolutely Lord Arlington's creature, and ungrateful enough.

Sir Joseph Williamson appears to have been a diligent and respectable public servant, who, in those times, could not have risen from so humble a beginning to the important situation of secretary, of commerce for business, or without some talents for continuance. Evelyn gives a disparaging account of him, from which the following is an extract. Having mentioned his appointment as secretary to Sir Edward Nicholas, he proceeds—Sir Henry Williamson is transferred to him, who, loving his ease more than business, though sufficiently able had applied himself to it, remitted all to his man Williamson, and in a short time let him into the secret of affairs, that, as he is a master of the French language, he may be able to advance him; and so by his subtility, dexterity, and ingenuity, he got now to be a principal secretary, absolutely Lord Arlington's creature, and ungrateful enough.

Sir Joseph was a musician, could play at 'jeu de poche,' and acted a part in acting a conversation, but inward with my Lord O'Brien, that, after a few months that gentleman's death, he married his widow, who, being sister and heir of the Duke of Richmond, brought him the 'Marquisate of Twickenham.' The marriage was conducted as they did before: She was much cenured for marrying so meanly, being herself allied to the royal family. (Evelyn's Diary, ii, 384.)

WILLIAMS (After Livingstone.)

WILLIAMS, SIR JOSPEH, a statesman of the reign of Charles II., was the son of the Rev. Joseph Williamson, rector of Birkeleyn in Cumberland. He came up to London, while yet a boy, in the capacity of clerk or secretary to the Board of Trade, and was agent for the arms of M. A. of St. Andrew's College, Oxford, in the service of whom he was admitted on the foundation of that college. He took his degree of B.A. in 1633, and immediately after went to France as tutor to a nobleman to whom he was recommended by Dr. Langbaine. He was afterwards elected a fellow of St. John's College, and in 1637, he took his Master of Arts degree.

After the Restoration he was appointed secretary to Lord Edward Nicholas, secretary of state, and on Sir Edward Nicholas being succeeded by Lord Arlington, he became secretary to the latter. He was appointed by Lord Arlington keeper of the State Paper Office in Whitehall. In 1667 he was appointed one of the clerks of the council in ordinary, and received the honour of knighthood. He was, in 1669, admitted into the most illustrious House of Lords, and in 1671, he was made a privy council to the earl of Sunderland and Sir Leoline Jenkins, at the treaty of Cologne. On the 27th of June, 1674, he was appointed secretary of state in the room of Lord Arlington, to whom, according to the custom of the time, he paid 6000l. in order to sit in the privy council. He was, in the same year, inducted into the privy council. The period during which Sir Joseph Williamson was secretary of state was one of subservience by Charles II. to the interests of France, with which power he entered into secret alliances, and of fear of the War Office. Sir Joseph Williamson was one of the first victims of excitement caused by the celebrated Popish plot, when the Tower, by the order of Commons, on the 18th of November, of granting commissions to Popish officers, but he was released by the king on the same day. On the 9th of February following he repaired the secretaryship of state, and was succeeded by the earl of Sunderland. In December, 1679, he married the baroness Clifton, widow of Henry, Lord O'Brien, and sister and heir to Sir Charles Stuart, Duke of Richmond, by whom he acquired large property and the hereditary office of high steward of Greenwich. Sir Joseph Williamson died in 1701, and his wife in the year following. He left 6000l. and a valuable collection of heraldic manuscripts and of notes, which was the property of the Library, Oxford; and he left 5000l. for the purpose of founding a mathematical school at Rochester, by which title he had been frequently returned to parliament. He died in 1701, and his heir, a brother of the earl of Richmond, in 1718.
However much these views may differ from those of modern physiologists, the idea of the brain being a congeries of organs is distinctly recognised. Whilst at Oxford Willis was a member of a philosophical society which is said to have lead to the foundation of the Royal Society of London. It was here, and at London, that he became the first to publish a work on the brain and nervous system, 'Pathologia Cerebri et Nervosi Generis Specimens,' Oxford, 4to. This work, in which he gave an explanation of the phenomena presented in convulsive diseases, hysteria, and hypochondria, was written at the request of the then governor of the hospital of St. Bartholomew's. He succeeded in explanation of the types of individuals, and not in the nervous system. To the attack of Hightmore, Willis repaid in a work entitled 'Adfectionum quam diciuntur Hystericae et Hypochondriacae; Pathologia Spasmodica vindicata,' &c., London, 1760, 8vo.

About the time of the publication of this last work, he lost his first wife, who was a daughter of Dean Fell. This event afflicted him much, and as a relief to his mind he conceived the idea of being a second marriage. He began to publish another work, which he never finished, entitled 'Pharmaceutica Rationalia,' of which the first paper was published at Oxford in 1762, and the second in 1765. This work, like his first, was a discussion of public questions, and especially of the principles of the chemical philosophy. His Latin style was neat and elegant. All his works abound in hypothesis, but they contain a great amount of sound observation, which renders them well worth perusal. Most of his works have passed through numerous editions, and the whole of them, with the title 'Opera Omnia Willisii,' have been published several times in this country and on the Continent. The comparative neglect into which they have fallen may be traced to the fact that but few of them have been translated into other languages. Willis was a man of great perception, and his writings in Sydenham, his successor in reputation, who rejected much of the hypothesis that burdened the works of previous writers.

Willis died of pleurisy, on the 1st of November, 1767. He was 70 years of age, and left an estate of 20,000l. He was performed in the church of St. Martin's Lane, every morning early, in order that he might attend before he visited his patients. At his death he left a bequest of 20l. a year for the continuance of this service. He also appropriated all his Sunday fees to charitable purposes. He discovered the mineral-spring at Astrop near Berkeley in Northamptonshire, and made it very famous, till the people of the place offending the well-known Dr. Radcliffe, made an attempt to destroy it, but to no purpose. He was a keen pupil in mathematics. He published the hypothesis that there were two English works said to be written by Willis, which were published after his death: the one 'A Plain and Exact Method for preserving (by God's Blessing) those that are well from the Infection of the Plague.' Written and dedicated from Dr. Willis's medical works. (Haller, Bib. Med.; Biog. Med.; Biog. Brit.; Aikin, Biog. Dict.)

WILLIAM BROWNE, an English antiquary of note, was born in the still more celebrated Dr. Thomas Willis, and by his mother's side of Robert Browne, of Frampton in Dorsetshire, was born at Blanford in that county, Sept. 14th, 1682. After passing through Westminster School, at which time he is said to have first imbued himself with a taste for the study of architectural and ecclesiastical antiquities, the neighbouring abbey being his favourite haunt, he entered Christ Church, Oxford, as gentleman-commoner. In 1677 he married Catherine, daughter of Daniel Elliot, of an ancient family, who bore him ten children.

This lady, who died in 1724, was herself a person of some literary pretension, and was author of a work entitled 'The Established Church of England the Catholick Church,' London, 1718, a performance which her husband appears to have thought very meanly of. On the Society of Antiquaries being formed in the year 1706, he became a member, and in 1740 the degree of LL.D. was conferred upon him by the university of Oxford. In the following year he testified his sense of the compliment by presenting to that body his valuable cabinet of English coins; he was also a consider- able benefactor to the British Library. In 1730 he became a fellow of MSS. Nor did his liberality confine itself to matters of that kind; for, in 1740, he contributed towards rebuilding Stony Stratford church, and in 1752 gave 200l. towards repairing the fine tower of that at Buckingham, for which he had presented to his alma mater nearly a half a century before, in 1705. He died at his seat, Whaddon Hall, Feb. 5, 1760.

That Browne Willis had a decided and disinterested passion for antiquarian researches cannot be doubted, since he devoted himself to it at a time when little regard was had to such studies, and indulged it beyond what prudence altogether warranted, considering the largeness of his family—five sons and as many daughters. As little doubt can be entertained that this was a taste for similar studies. His greatest and most important work is his 'Survey of the Cathedrals of England,' 3 vols., 4to., with plates, which appeared in 1727, 1730, and 1733. Of his 'Notitia Parliamentarum,' the conclusion was not published till 1750, although the first part had been printed in 1715. His last production was a 'History of the Town of Buckingham,' 4to., 1755. (Chalmers's Biographical Dictionary; Nichols's Literary Anecdotes.)

WILLIS, FRANCIS, was a student of Brazenose College, Oxford, and took holy orders in the year 1740. He was soon after appointed to the living of St. John's, Wapping, and afterwards to Greatford in Lincolnshire. Having a taste for the practice of medicine, he used to prescribe himself for those whom he thought too poor to pay for it, and he was often called to those in the neighbourhood so much, that in his own defence he obtained the degree of doctor of medicine from Oxford in 1759. His medical and philosophical studies induced him to take up the subject of insanity, and he was very successful in his treatment. It was on an occasion that he was asked in to take charge of George III., when the king was for the first time deprived of the use of his mental faculties. His treatment was successful in this case, and gained for him the reputation of a great physician. He is credited with the cure of a maniac and a maniac ' would make him quail more effectually than a chain or manacles.' (Wenslow, Physic and Physicians; Grant's Mag., vol. 77.)

WILLOCK, WILLOCKS, or WILLOX, JOHN, one of the earliest champions of the Reformation in Scotland, is supposed to have been born in Ayshire, about the beginning of the sixteenth century, and to have studied at the University of Glasgow in his earlier years. Nothing is known as to the period of his birth, but whether Franciscan or Dominician is not clearly ascertained. He visited England in the year 1541, having before that time become a convert to the opinions of the Reformers, and he was there subjected to imprisonment, as a matter of safety, till the second part of the same year. He was afterwards chaplain to the Duke of Suffolk, and on the accession of Mary of England he fled to Friends of William the Companionship in the suppression of the six articles of Henry VIII. He became Afterwards chaplain to the Duke of Suffolk, and on the accession of Mary of England he fled to France, where he was there patronised by the Duchess Anne, who sent him in several missions to Scotland. About the year.
he returned to reside in his native country, and preached the
doctrines of the Reformation in the town of Ayr. He
did not return to his own church, but continued to preach as a
debat with the principal champions of Catholicism in
Scotland. In 1559 he was cited, along with other reformers,
to answer for the opinions promulgated by him, and was
outlawed for not appearing; a circumstance attributed with
apparent justice to the influence of heresy on the part of his
Queen Regent. He now rose in popularity; large masses of
people flocked to his ministrations; and as the head of a
party he became sufficiently powerful to cause the rejec-
tion of a proposal by the humblest Regent, that the Regent
and his constant service might be placed at the
option of the people. He was one of the four ministers
appointed to assist the council of government on the depo-
sition of the Regent. In 1561 he was appointed one of the
superintendents who succeeded to some of the duties of the
Catholic bishops. He spent a great part of the remainder
of his life in England, but was moderator of several Gene-
ral Assemblies in Scotland from 1563 to 1568. The time
of his death is not known.

(Wadrow, Biographical Collections printed for the
Maitland Club, pp. 99-116, 449-453.)

WILLOUGHBY, SIR HUGH. The history of this un-
fortunate voyager is very obscure. A portrait is shown at
Wollaton Hall, Nottinghamshire (an ancient seat
belonging to the family of Wollaston), and in Derbyshire
that of Sir Hugh. Collins conjectures that 'Sir Hugh Willoughby,
Knt., of Ribby in Derbyshire, grandson of Sir Henry Willoughby,
who died in 1528, by his son William, who died before his
father, was the discoverer.' If this be true, Sir Hugh was the son of
William, by his wife Helena, daughter and co-heiress of Sir John Egerton, of Wil-
ne Hall in the county of Chester, and had himself a son
Henry (created a baronet by James I. in June, 1611), by his
wife Jane, daughter of Sir John, Bart., of Ribby in
Northamptonshire.

Clement Adams, in his narrative of Chancellor's voyage,
moments Sir Hugh in these terms:— 'To which office and
place [commander of the expedition fitted out by the mer-
chants adventurers in 1558], although many men
so experienced in matters of this sort himself considered, yet
one Sir Hugh Willoughby, a most valiant gentleman and
well born, very earnestly requested to have that care and
command committed unto him; of whom before all others,
both by reason of his goodly personage (for he was of
a tall stature) as also for his singular skill in the services
of war, the company of merchants made greatest account;
so that at last they concluded, and made choice of him
for the governor of this voyage, and appointed to him the
administration and command over all the
people. This appointment was confirmed in a licence to
discover strange countries from the king Edward VI., of which
a MS. copy is contained in a volume (Fauins, C., ii.) of the
Cotton collection in the British Museum.

This vessel which we have been able to
discove is that contained in the first volume of Hak-
luyt, purporting to be the journal of Sir Hugh Wil-
looghe himself, and incidental notices in Clement Adams's
account of Chancellor's adventures, and in the voyages
of Burrough and Jenkinson in 1576, in the same collection.
Among the Cotton MSS. already alluded to (Otho, E., viii.)
there is a list of the three ships fitted out for the expe-
dition, and of the names and offices of all persons em-
baed in them; and a journal of the voyage from the 10th
of May to the end of September, 1558. It has been much
injured by fire, but enough remains to show that it corre-
ponds exactly with what is printed in Hakluyt's work.

It appears to be in the handwriting of Michael Lok. Pur-
cussion of it (translated by him 469) ascribes the authorship
of Willoughby, his kinsman, subscribed by Sir Hugh, which will
now have, and keep as a relic of that worthy discoverer.

The expedition of which Sir Hugh Willoughby was ap-
nointed commander was fitted out by the mystery
company of merchants adventurers for the discovery of
regions, dominions, islands, and places unknown,' whose
governor was Sebastian Cabot. It consisted of three ves-
sels:—the Bona Speranza, of 120 tons, commanded by Sir
John Arden; the Speranza, of 110 tons, the pilot-ship, a
master and mate, and 36 seamen; the Edward Bonaventure,
Richard Chancellor, pilot-major of the fleet, captain of
160 tons, with a master and mate, minister, surgeon, and
50 seamen; and the Bona Confindentia, of 90 tons, under a
master and mate, with 22 seamen. The vessels were vic-
tually allowed for fifteen months. Six merchants embarked in
the admiral's ship, nine in the pilot-major's, and three in
the third vessel, and carried the sum of 2000l., which was
vested in a council of twelve. The council consisted
of the admiral and pilot-major, the masters of the three
vessels, the minister, three merchants, and the three masters'
mates.

The expedition sailed from Deptford on the 10th of May,
1553, but was detained in the river and off the coast by
baffling winds till the 23rd June. It fell in with the Nor-
wegian coast; some way south of the Ros Island, on the
24th of June, and then that the Regent, as the next best
station of the Danes in Finmark, the vessels were separ-
bated by a storm. Next day the Bona Speranza and the Bona
Confidentia once more joined company, but Chancellor's vessel
did not again fall in with them. Clement Adams relates
of their separation, derived from some mariners of the
Edward Bonaventure, is as follows:— 'The very same
day in the afternoon, about four of the clock, so great a
tempest suddenly arose, and the seas were so outrageous,
that the ships could not keep the commanded course, but some
were per force driven one way and some other, to the
great peril and hazard. The general with his loudest
voice cried out to Richard Chancellor, and earnestly re-
quired of him not to return; but if he went on in that
way, which he would keep company with him if he sailed still so fast, for
the admiral was of better sail than his ship. But the
admiral (I know not by what means) bearing all his air
was carried away with so great force and swiftness, that
he did not lose his patience; he corrected the captain
ship also, with the same storm and like rage, was dispersed
and lost us. The ship-boat of the admiral (striking against
the ship) was overwhelmed in the sight and view of the
marmers of the Bonaventure; and for them that went
abroad they meant not to touch, and as to the weather,
nothing of the ships what has become of them.' The narrative is
the diary attributed to Sir Hugh Willoughby corresponds
with this account in all essentials.

It appears from many journals referred to, that the Bona
Speranza and Bona Confindentia were tossed about in the
North Sea from the 30th of July to the 15th of September,
vanitily attempting to make Wardhus. On that day the
entered a harbour which we learn from Jenkinson was the
mouth of the river Arina, six days' sail west of Wardhus,
and one day's sail west of the Svisatoi Nos, the western
headland of the White Sea. 'This haven,' says the journal,
'runneth into the main about two leagues, and is a
breadth half a league, wherein are very many seal-bales
and other sea-fowre; over all the headland are very
great deer, foxes, with divers strange beasts, as elk
and such others, which were to us unknown and also won-
derful. There remaining in this haven the space of
sevennight, seeing the year far spent, and also the
weather was wettest, snow, and frost, and the sea had been
the depth of winter, we thought it best to winter there.
Wherefrom we sent out three men south-west to
search if they could find people, who went three days
journey, but could find none. After that we sent the
three westward four days' journey, which also returned
without finding any people. Then sent we three
south-east three days' journey, who in like sort returned
without finding of people or any similitude of habitation.
They entered the harbour of death (as it is called in the
margin of the Cotton MS., Otho, E., viii., p. 15) on the 18th
of September: they remained a week before resolving to
winter there; and they sent out three exploring parties, two
of which appear to have been at least six and one eight
days absent. This having been done, the date of the
Speranza's will, which Purchas says was in his possession, shows that some of the party must have
been alive in January, 1554. Nothing more is known of
their fate. In 1557 Stephen Burrough, who was with
Colombo to search for the Esperanza, the Bona Confindentia, and the Philip and
Mary, another ves-
bel belonging to the merchants adventurers, which
was also missing. At Kegor he learned from a Dona-
man, who spooned upon the ship, which was
in the English, and that the Bona Confindentia was lost, and that he
didn't bought her sails for his ship. Of the fate of the Bona
Esperanza he does not appear to have obtained any
intelligence. Anthony Jenkinson, in his account of his
voyage to Russia, written apparently between January and
April.
WILLUGHBY, FRANCIS, was the only son of Sir Francis Willughby, Knight, and was born in 1635. His father, who was in the service of the Duke of York to the education of his son, who was so diligent in his studies that it was feared he would injure his health. He early acquired great knowledge both of the classics and mathematics, and in the various branches of natural science. Willughby had a great passion for science, which, and his love of travel, led him to visit the Continent, and took his degree in Bachelor of Arts in 1656, and of Master of Arts in 1659. It was here that he became a pupil of John Ray, and a lasting friendship was soon formed between the master and pupil. Willughby had a great passion for zoology, to which he devoted himself, and the fruits of their labours were so great that they took great interest in the progress of natural science. Ray had at this time made great progress in the study of botany, and had already begun to reduce to harmony the confused facts which had been heaped together in a mass by the botanists of his day. Each time that a new species was discovered, Willughby was to do the same for zoology. The Pindarts of Gesner and Aldrovandus had been published, but the question that occurred to his mind was, How much of all this is true, and how much is false? To answer this question the science of zoology as it then existed, he set to work. For this purpose he went to Oxford in 1660, in order that he might consult the works on natural history in the libraries there. Shortly after the death of the Duke of York, he was obliged to resign his fellowship and leave Cambridge. The consequence was that the two friends made a tour on the Continent, visiting France, Spain, Italy, Germany, and the Low Countries, and the researches and observations on natural history: Ray examined plants, whilst Willughby attended to the animals. They returned laden with treasures, which Willughby immediately commenced working at, for the purpose of publishing a large work on ornithology, and a monograph of plants, with the help of the Duke of York, who was about to make a voyage to America, in order to add to his knowledge. But he died, in the midst of all his labours and in the prime of life, on the 3rd of July, 1672. He had published little, and thought his labours too imperfect to justify their publication. However, his friend Ray recommended one of his works, for three reasons, that he should allow him to publish his works: first, the glory of God; secondly, the assistance of others in the same studies; and thirdly, the honour of their native land. Upon receiving permission of his executor, and Ray became their editor. He also left Ray one of his executors, and committed to him the charge of educating his two sons Francis and Thomas. Francis, the elder, who was then only four years old, died in 1673, and Thomas subsequently became Lord Middleton. For this office, which Ray sacrificially fulfilled, Willughby left him sixty pounds a year, which constituted the chief part of this great man's income throughout his life.

Willoughby was the first writer to use the word "ornithology" in its modern sense. His work, "On the Ornithology of the Birds," was published in 1678. It contained a wealth of information on birds, as well as other animals, and was a significant contribution to the field of natural history. Willoughby's work was translated into French, Latin, and many other languages, and it influenced the work of later naturalists and ornithologists.

Willoughby's death was mourned by his contemporaries, and his name is remembered today as a key figure in the history of natural history. His legacy lives on in the field of ornithology, and his work continues to be studied and admired by scholars and naturalists alike.
trouble with the plates, they are too inaccurate to be of use at present. But the letterpress is a perennial source of observation on the habits and structure of birds. In 1688 Ray edited a second work on the same plan, embracing the fishes. This was published at London, in folio, with the title 'Historie Fiscum Libri Quatuor.' The descriptions in this work are good, and Cuvier states that it contained many observations on the Mediterranean fishes that could not be found elsewhere. In all his descriptions Willughby was very careful in distinguishing specific characters, and in this way he corrected many of the errors of preceding writers.

When Ray were early Fellows of the Royal Society of London, and Willughby contributed some papers to the 'Philosophical Transactions' before his death. Two of these were published in the 'Transactions' for 1671; one of them was on a 'New Wasp on Ophicia Chrysomene,' and another on 'The Habitations of Kinds of Bee lodged in old willows.' Ray afterwards contributed many papers on insects, of which the substance had been prepared from Willughby's manuscripts.

He had been an active member of the 'Ornithologia,' has left behind him a beautiful memorial of the estimation in which he held his friend in the summary he there gives of his character. He seems to have added to habits of excessive industry and a rare philosophical genius, every virtue. It is not easy to say he was useful to his family and friends, in his life. The influence of Willughby undoubtedly, under the direction of Ray, has been very great in every department of zoology, and had he lived to have laboured more, and to have developed the great principles of classification, of which Ray did much to clear up, it might have been said that the foundation of both sciences was laid at the same period in Great Britain. (Ray.)

(Derham's Life of Ray; Ray's Preface to Willughby's Ornithologia.)

WILMOT, JOHN, EARL OF ROCHESTER, was born at Ditchley (Oxfordshire), 10th of April, 1647, or, according to Burnet and Wood, in 1648. He was the son of Henry, Earl of Rochester, a brave royalist in the civil wars and Protector of Charles II. in his exile. He was educated in the free-school at Burford, and at Wadham College, Oxford, where he showed remarkable talents. At school he acquired an exact knowledge of Latin, and became familiar with the best authors of the Augustan age, in whose writings he ever afterwards delighted. At college he was placed under the charge of Dr. Blandford, afterwards bishop of Oxford and of Worcester, but he abandoned himself to pleasure rather than to study, and, breaking off his course of reading at an early age, set off upon his travels, especially to Germany and Italy. He returned to England in the eighteenth year of his age, and presented himself at the gay court of Charles II., where the graces of his person and the liveliness of his wit and fancy made him an acceptable companion. He also sought opportunities of distinction in that circle, and was elected a fellow of the earl of Sandwich, in the Revenge, commanded by Sir T. Tiddiman, and displayed great courage in the attack made on the Dutch fleet in the port of Bergen. In the following summer he again went to sea, under Sir Edward Spragge, and in the midst of an engagement voluntarily carried away a despatch in an open boat, a service of great peril, which he executed with daring and judgment. These warlike deeds gave him a reputation for courage, which however, he did not sustain at close quarters, and was occasionally sneaking away in street quarters, and of evading duty, which he had provoked. This impudence suggested the lines of Sir C. Scrope:—

"Thou canst bark so man's fame with thy all word; Thy prate is half as harmless as thy word."

He is said to have entered upon a court life free from habits of intemperance, but his convivial disposition, his extreme youth, and the contagious example of a profligate court seduced him into such excesses that, as he assured Dr. Burnet, for five years together he was continually drunk. His fancy was more luxuriant when inflamed by wine, and his companions encouraged his excesses the better to enjoy his wit. In the midst of drunkenness and debauchery, his talents, by extraordinary business, he uncommonly found time for poetry. Its character naturally took the cast of his life and habits: personal satires and drinking and amatory songs, were the least ignoble fruits of his genius; licentious and obscene verse, the more reflection of his life, was his ordinary recreation; and his levelling wit, and with the grace and spirit of his verbosity, only caused us to regret the misapplication of his abilities.

The services of his father and his own favour at court obtained for him the office of gentleman of the bed-chamber and comptroller of Woodcock Park. But although his convivial talents rendered him agreeable to the king, his satires often gave offence. On one occasion, while drunk, he put into the king's hand a paper which he supposed a libel he had written, in which happened to be a satire upon King Charles himself. At another time he ventured so far as to scribble upon the door of the king's bedroom the well-known epigraph:—

Here lies our sovereign lord the king.
Whoever sitteth on his throne
Shall be for evermore his enemy.
of the honey are attributed to the great forests of im- 
etrees, of the flowers which the bees are very fond.

Though a great deal of honey is used for mead, or tipep, 
and for malinek, a beverage composed of honey and rasp-
berry juice, large quantities are exported. The fishing is 
of little importance. The abundance of fresh-water fish 
in the rivers and lakes, such as perch, pike, carp, but 
there is none for exportation. Sea-fish are obtained from 
Courland and Livonia.

There are vast forests of oak, fir, ash, beech, lime, will-
ower, and maple, and among them we find toadstools 
treating received finally its antient name of Wilna. It 
is bounded on the north by Courland, on the north-
west by Vitepok, on the east by Minak, on the south by 
Grodno, on the south-west by the kingdom of Poland, 
and on the west by Prussia, and on the north-east by 
the Baltic. Its area is 24,403 square miles, and the popula-
tion 1,315,800 inhabitants.

Flax.—The economy of Lithuania is essentially agri-
cultural, and the yielding of flax is of great pro-
ingress. The raw flax is consumed in our own manufac-
tories, but little attention is paid to the flax-growing 
elements, and a great deal of it is exported to Russia, 
where it is used for the manufacture of paper.

Agriculture.—Of all the occupations which support the 
inhabitants of Lithuania, agriculture is the most impor-
tant. It is the chief productive industry, and it is 
controlled by the government. The Lithuanians are 
remarkable for their hardy nature, and they work 
diligently to produce the greatest possible yield from 
their land. They cultivate various crops, including 
wheat, rye, barley, oats, potatoes, and hemp.

The climate of Lithuania is moderate, with long, 
cool summers and mild winters. The soil is fertile, 
and the Lithuanians are skilled farmers. They 
produce a large amount of grain, including 
barley, wheat, and rye. potatoes are also 
common, and they are used in the local cuisine.

There are many lakes and rivers in Lithuania, 
which provide a source of water for irrigation and 
irrigation. The Lithuanians are skilled at 
irrigation, and they use it to maximize their yields.

Fish farming is also important in Lithuania, 
with many lakes and rivers providing a source of 
fish. The Lithuanians are skilled at fishing, 
and they use it as a source of food.

Manufactures and Trade.—Lithuania has a 
long history of manufacturing, particularly in 
textiles and metals. The Lithuanians are 
skilled in weaving, and they produce a variety of 
textiles, including cloth, linen, and 
textiles. The Lithuanians are also skilled at 
metalworking, and they produce a variety of 
metal goods, including 
and 
iron work.

Trade is important in Lithuania, 
with many goods being imported and exported. The 
Lithuanians trade with neighboring countries, 
particularly Russia, Poland, and 
Prussia. The Lithuanians are 
skilled at trading, and they use it to 
support their economy.

The population of Lithuania is 
diverse, with many different 
ethnic groups. The Lithuanians are the 
most numerous, followed by 
Russians, Poles, and Germans. The 
Lithuanians are skilled at 
agriculture, and they use it to 
support their economy.

The government of Lithuania is 
strongly supported by the 
people, and it is 
skilled at 
administering the country. The 
government is 
organized, and it is 
skilled at 
running the country.
the great Krusenstern, appointment He a quam Musical 412, obscure CommenuUio has 'was garden since teachers in 1832, burnt by

Trok, the second capital, is situated on a lake 17 miles to the west; it has 4000 inhabitants. Kowel is a considerable town, situated at the conflux of the Wilia and the Niemen, and surrounded on all sides by those rivers: it was here that the main body of Napoleon's army entered Russia on the 24th, 25th, and 26th of June, 1812. It is one of the most ancient towns of Lithuania. There are several churches, and some houses built in the Gothic style. Kreidany, with 6000 inhabitants, is a very respectable town; all the houses however are of wood.

WILNA, the ancient capital of Lithuania, now that of the government, is situated in 54° 43' N. lat. and 23° 10' E. long., at the conflux of the navigable river Wilia and the Wilieka, and is surrounded with picturesque hills. The streets, which are crooked and narrow, bear witness to its antiquity. On an eminence called the Castle Hill are ruins of an immense palace of the Jagellons. The town-hall does great credit to the talents of the Polish architect Guczewicz; the ascent, the palace of the government, and some palaces of the nobility are handsome buildings. Among the churches the cathedral, dedicated to St. Stanislaus, is the most worthy of notice. It was built in 1367, on the spot where the sacred fire had formerly been lighted in dedication of the Lithuania god Perkūnas, the master of the thunder. Besides the Roman Catholic churches, there are several Jewish synagogues, two Protestant churches, two Greek churches, and a mosque. There are in all forty churches.

The town of Wilna, founded as a college of Jesuits in 1578, and raised to the rank of a university, was not however permitted to teach medicine or jurisprudence. In 1773, when the order of the Jesuits was suppressed in Poland, its property was assigned to the schools, and the univeristy was empowered to impart all the branches of human knowledge. Political events caused it to decline till 1803, when the emperor Alexander gave it new statutes and an increased revenue; it was in a very flourishing condition when, in consequence of the revolution of 1812, it was suppressed in May, 1812, and its library of 200,000 volumes was transferred to St. Petersburg. There remain only a medico-chirurgical academy, with the botanic garden, the observatory, and a theological seminary. There are no manufactures of importance but a considerable trade. The population is 68,000 inhabitants, of whom nearly one half are said to be Jews.

Troc, the second capital, is situated on a lake 17 miles to the west; it has 4000 inhabitants. Kowel is a considerable town, situated at the conflux of the Wilia and the Niemen, and surrounded on all sides by those rivers: it was here that the main body of Napoleon's army entered Russia on the 24th, 25th, and 26th of June, 1812. It is one of the most ancient towns of Lithuania. There are several churches, and some houses built in the Gothic style. Kreidany, with 6000 inhabitants, is a very respectable town; all the houses however are of wood.

WILSON, FLORENCE, is the name generally given to an author who is spoken of by his contemporaries only by his designation, Florence Voluzenus. The vernacular name Wilson has been attributed to him solely because, being a Scotchman, no other common to Scotland approaches so near to that which he assumed. He has been supposed that he was called Wilson, because he was patronised by the great cardinal and in a vernacular letter which has been preserved he signs himself Voluzenus. He is supposed to have been born near Elgin, in the county of Moray, about the beginning of the sixteenth century, and to have studied at the university of the College of Aberdeen. He afterwards studied at the university of Paris, where he became tutor to a son of Cardinal Wolsey's brother. Losing this employment at the death of the cardinal in 1530, he was patronised by the cardinal of Lorraine, a suburb of Paris. In 1534 the bishop went on an embassy to Rome, but Wilson, who was to accompany him, was kept by sickness at Avignon. Understanding that Cardinal Sadolet desired a Latin scholar to teach a grammar-school at Carpentras, the metropolis of his diocese, he paid his services in that capacity. Sadolet has left an interesting account of his interview with the wandering student, and of his surprise in finding one so well versed in polite learning coming from so distant and obscure a country as Scotland. Wilson received the annual salary of seventy crowns, and entered on his duties in the year 1535. His earliest work, the publication of which is only known from its being entered in the "Bibliotheca Thesauri," and mentioned by Gesner, was published at Lyon in 1535. It is called "Commentatio quaedam Theologica, aut crudelitatum praecipuorum." In 1543 he published the work by which he is best known, "De Animis Tranquillitate Dialogus." The scene is laid in a garden near Lyon, and three interlocutors greatly debate on the subject of tranquillity of mind, in the manner of the dialogues of Cicero. It was republished at Lyon in 1537. A third edition was printed at Edinburgh in 1707, under the superintendence of Reidman, and a fourth at Edinburgh in 1751, edited by Principal Wilson.

In 1546 Wilson formed the design of returning to Scotland; it was opposed by the dean of the cathedral of Wilna, where he died, "quae procul a patria," as Buchanan laments in some laudatory lines addressed to his memory. Dempster mentions among Wilson's works, "Philosophia Arithmetica," on which he supposes him to be insufficient authority for such a work and another existed.

(Mackenzie, Lives of the Writers of the Scot. Nation, iii. 29-34; Irving, Lives of Scottish Writers, i. 23-34; Chambers, Biographical Dictionary of Eminent Scotsmen.

WILSON, JOHN, Doctor in Music, was born at Faresham in Kent, in the year 1594. He was first a student of the Chapel-Royal to Charles I., and afterwards Seruit in Ordinary to the same king. He was esteemed the best organist in England, and was a most zealous attendant on the king," Sir John Hawkins says, "he frequently played to him, when the king would usually Lean on his shoulder." He was created doctor in music at Oxford in 1644, and in 1650 was elected professor of the same science at Cambridge. He is supposed to have had apartments in Bachelat College, where, assisted by the royalists, he excited "such a love of music as is still measure accounts for that flourishing state in which it long subsisted there; and of which Anthony Wood speaks in his "Lives of Eminent Painters," after the Restoration he entered into the service of Charles II., succeeding the famous John Lawes, and died in 1673. He composed much sacred music, and set many of the psalms of Horace, as well as select passages from the works of Claude and Petronius; and, in a few of his works now are to be met with, and of these the most pleasing are published in Playford's "Musical Companion," 1663, and interesting and excellent collection of vocal music, which is becoming rare.

WILSON, RICHARD, R.A. This great landscape-painter was born of a respectable family at Fingen in Montgomeryshire, in 1713. He was the third son of seven children, six sons and one daughter. His father was a Mancunian clergyman of the name Wilson; it was in 1751 that he painted a large picture of the princes of Wales and his brother the duke of York, for their tutor Dr. Hayter, bishop of Norwich.

After practicing some time with success as a portrait-painter in London, he went, in 1748, to Italy to study the great masters. He afterwards resided in France, but was shortly afterwards called to the livings of Mold in Flintshire. Young Wilson showed very early a taste for drawing; and gave much promise, that his relation Sir George Wyne took him to London and placed him in the studio of Thomas Wright, who lived in Covent Garden. With the master he made great progress; but nothing is known of his earlier studies. He must however have attained some rank as a portrait-painter, for in the year 1769 he painted a large picture of the princes of Wales and his brother the duke of York, for their tutor Dr. Hayter, bishop of Norwich.

his portrait for a landscape. Wilson did not do as many painters have done, that is, copy the works of celebrated masters, but he went immediately to the source of all art, and confined his studies to nature. By this course he attained that bold natural yet classical style for which he is distinguished, avoided the acquisition of adventitious beauties, and became a member which generally arises from the too partial study of favourite masters.

He returned to London in 1750, after an absence of six years. In 1760 he exhibited, in the great room at Spring Gardens, his celebrated picture of Niobe, which was purchased by Wilson's brother. This work established his reputation in England as one of the first landscape-painters of his time. In 1765 he exhibited in the same place a View of Rome from the Villa Madams, which was the subject of the then Marquis of Bœck. He was one of the first members of the Royal Academy, which was founded in 1788; and at the death of Hayman, in 1770, he was appointed librarian in his place: this appointment brings a very small emolument with it, yet, small as it is, Wilson solicits the place; for although a few discriminating connoisseurs purchased some of his best pictures, he was neglected by the public, and was in a state of indigence compared with the majority of his fellow-members of the Academy. Many of the academicians were glad to lead up to the dealer, who, opening a door, pointed to a pile of landscapes against the wall, and said, "Look ye, Dick, you know I wish to oblige you; but see, there's all the stock I've paid for these three years." And it is a fact that some of these landscapes, for which Wilson had been since sold for nearly as many hundreds, thus verifying the prophetic consolations of Peter Pindar to the poor painter, in his "Odes to the Academicians": —

"Wilson's art
With hold the empire o'er my heart,
By Britain left in poverty to bear —
But, honest Wilson's humble head,
Emolument thou shalt find.
And for a house how canst thou taste to rear —
Those start at thy prophetic lines!
They are but indifferent for those times;
Wait till then has been a hundred year!"

The following instance will show how unnaturally Wilson was appreciated even by those who might be expected to know better: — He painted a picture of the Royal Gardens of Earls, which being shown to the Grand, expressly for George III., and after the king had kept it for a short time it was returned to him; the king however had probably little to do with the transaction. Peter Pindar (Dr. Wolcott) bought the rejected picture.

This fortunate chance enabled him to sell his works, that when one met with a ready sale and more than usual attention, he repeated it; and he painted some subjects as many as four and even five times, making only very slight alterations: he painted five pictures of Mackenas's Vase, with the following principal works: — Niobe; Phaeton; large view of Rome; Villa of Macenas at Tivoli; large view on the river Po in Italy; a companion to it, called Nolitude; View on the coast of Baise; View on the Strada Nomentana; Hadrian's Villa; several views near Rome, Temple of Bacchus near Rome; View on the Tiber; View of the Bridge of Kinc; the Lake of Nemi; Ciceria at his Villa; View of Anconae; Broken Bridge of Narni.; Ruins on the coast of Baise; Temple of Venus at Baise; Island in the Gulf of Venice; Tomb of the Horatius and Cursati; Apollo and the Seasons; and numerous others which generally arise from the too partial study of favourite masters.
W I L

Hence his fire-side was a solace to the misanthropic painter, than whom no mortal of his transcendent talent had ever gathered so much of a claim. Perhaps it is injurious to his memory to write him down misanthropic; certainly he became a cynic—and who but must lament the cause? Wilson was one of those rare geniuses who appear formed to develop the almost hidden excellence of every season of art and continued unabated when his superiors in rank; for he unfortunately lived when his lofty conceptions of art surpassed the comprehension of his contemporaries, which inducing indifference and neglect of his extraordinary talent, naturally begot an asperity in his proud manner. He was a clever man, whether a professor of a liberal science or skilful mechanic; and neglected talent could always draw largely upon his sympathies. Thomson was a man exactly suited to his taste; he was humorous, good-tempered, and speculative in his own profession; and being, as is said before, not much hurried, Wilson, when under the influence of the spleen, would quit his easel, and march off to Exeter Change, when, under cover of Thomson's stall, he would sit and meditate in the evil dispensations of the Fates to men of mind. Wilson frequently took to his way, and so the pipe with Thomson; and sometimes Garrick was one of the party.

(T. Wright, Some Account of the Life of Richard Wilson, R.A.)

WISLONIA, a genus of plants belonging to the natural order Convolvulaceae. This plant was discovered by Brown in New Holland, and named by him in honour of John Wilson of Kendal, who published 'A Synopsis of Botany.' Ray's Method in 1743. In this work many new stations of plants were indicated, and notes added upon the economical and medicinal uses of medical plants. Wilson was in an humble condition of life, and made great sacrifices for the purpose of enabling him to pursue his botanical studies. He was so anxious to possess Morris's work on plants, that he was about to sell his only cwt to purchase it, when a beneficent lady in his neighbourhood presented him with a copy.

WILTON, JOSEPH, R.A., a successful sculptor in his day, and the fashionable precursor of Nollekens in English bust-making. He was born in London in 1722; his father was a wealthy plasterer, and when his son was of a sufficient age, he sent him abroad to study sculpture. Wilton studied at Florence, and returned to England. He came in contact with Cipriani, the architect, and a clever modeller of the name of Capizziolo, who assisted him in some of his works. When the Duke of Richmond opened a gallery for students in art, in Spring Gardens, he appointed Cipriani and Wilton the directors of it. When he died in 1792, Cipriani was appointed Tutor, and he modelled the coronation coach of George III. Of his public works the principal are—the monument to General Wolfe in Westminster Abbey, of Admiral Holmes, of the Earl and Countess of Monbran, and of Stephen Hales. He made busts of Bacon, Cromwell, Newton, Swift, Wolfe, Chatham, and Chesterfield, besides many others. All his works were, like those of Roubili, admirably worked in the marble, but he showed little taste in his compositions; they were too crowded and too minute in accessories, and every species of ornament was forced upon him, and he adapted design for sculpture. Wilson however made a large fortune and lived in great style. He kept almost an open board, and among others, Wilson, the landscape painter, and Bentley, the lexicographer, were often seen making their way to Wilton's at dinner-time. He had a very beautiful daughter, who was married to Sir Robert Chambers.

In the Royal Academy there is a bust of Wilton by Roubilli, the present of his daughter Lady Chambers. Wilton was one of the founders of the Royal Academy. He died in 1803, in his 81st year.

(Cunningham, Lives of British Painters, Sculptors, and Architects.)

WILTSHIRE, an inland county of England, bounded on the north-west and north by Lancashire, on the south-east by Hampshire, on the south-west by Dorsetshire, and on the west by Somersetshire. The county is of very compact form, approximating to a quadrangle, having its angles respectively near Lechlade, Yatton near Malmesbury, Southwell, and Dodman near the verge of the New Forest. There are several small detached portions, surrounded by the adjacent counties of Gloucester and Berks. These detached portions consist of part of Wrotham, and part of the estate of Hakon, situated in Hurst parish, Dibnam lying in Shifnal in Shropshire, and Swallowfield in Berkshire, and parts insularated in Berkshire; Kingwood parish, near Wootten-under-Edge, insularated in Gloucestershire; and Poulton parish, between Cirencester and Fairfield, also insularated in Gloucestershire. The county, including all its detached portions, is situated betwixt 50° 55' and 51° 43' n. lat., and between 1° 32' 20" W. long., and 1° 49' 30" W. long. The greatest dimension of the county, measured north and south, is from the border of Gloucestershire, between Cirencester and Fairfield it is 40 miles; and the width, between the north-north-west and the south-south-east, from the nearest point of the border of Hampshire at Downton Bridge, between Southam and Ringwood. The greatest breadth from east to west is from the junction of the three counties of Hampshire, Berkshire, and Wiltshire, at Inkpen Beacon, to the nearest point of the county of Gloucestershire, 63 miles. These dimensions are of course the main part of the county, without the detached portions. The area, including the detached portions, is estimated at 1,887 square miles; the aggregate areas of the several parishes are estimated at 4,195 square miles; the trilling discrepancy in these estimates is not accounted for. The population of the county at the several enumerations of the present century was as follows:—1801, 185,107; 1811, 193,828; increase 5 per cent. 1821, 181,307; increase 15 per cent. to 1831, 184,800; increase 82 per cent. In respect of area it is the fourteenth of the English counties, being 99 square miles smaller than Sussex, the county next above it, and 24 square miles larger than Shropshire.

Surface and Geology.—The geological formations of Wiltshire consist chiefly of the cretaceous and coal series, with the intermediate beds; in the south-eastern corner the chalk is covered with the tertiary formations of the chalk-basin of the Isle of Wight. We shall first notice the chalk formation, which may be considered as comprising a considerable portion of the country, striking geological feature of the county, forming the extensive down lands which overtop the eastern, central, and southern parts. The chalk district of Hampshire and Wiltshire constitutes the centre of the chalk formation in England, from which exceed four great branches. The first branch is the chalk range of the Chiltern hills, Dumbale and Rounton downs, &c., extending through Berkshire, Buckinghamshire, Bedfordshire, Hertfordshire, Cambridgeshire, Essex, Hants, and Wiltshire, across the Wash, reappearing in Lincolnshire and Yorkshire, and terminating in Scarborough Head; the second branch is the North Downs of Hampshire, Surrey, and Kent; the third the South Downs of Hampshire, Sussex, and Kent; the fourth the North Downs of Dorsetshire, passing through the counties of Dorset, enclosing between them the trough of Poole. The Wiltshire portion of the great central chalk district is divided into two parts by the vale of Pewsey, where the
green-sand occupies the bottom of the valley, and is skirted on each side by the chalk-hills. As this valley extends eastward as well, it will be convenient to describe portions first, within the chalk district as the northern and southern districts; Marlborough downs belong to the northern district; Salisbury Plain belongs to the southern district.

The chalk district is bounded by a line entering the county from Berkshire at the village of Bishopstone, and passes south-west by the villages of Little Hinton, Wanborough, Liddington, Badbury and Chiseldon, and then along the hills above Broad Hinton and the Winterbourne, Avaury. From Avebury, running south-west to Cherhill, then south-west to the neighbourhood of Edington or Heddon, its westernmost point, from which the boundary returns in a tolerably direct line eastward by Bishopstone, All-Cannings, Stanton Fitzwarren, the All-Cannings, and then by a northerly circuit of Tottenham Park near Great Bedwin, to the border of Berkshire at Great Shalbourne. The boundary may be traced throughout by a tolerably steep escarpment over-looking the surrounding county. The included chalk district is divided into the parts on the west, running east and west, through which the Kennet passes from Avebury to Hungerford; and the northernmost of the two parts is again divided by a valley running north and south, and divided by a small feeder of the Kennet. The easternmost part is a continuation on the north side of the Kennet to the south of Marlborough.

The southern part of the chalk district forms an elevated platform, and is considered as a type of the Vale of Pewsey. The northern part of the chalk is the site of a number of small hilly outcrops, known as the Downs or the Westwood, which are partly occupied by the Great Bedwin. The boundary of the chalk district is marked by a steep escarpment over the vale of Pewsey. The northern part of the chalk district forms an elevated platform, and is considered as a type of the Vale of Pewsey. The southern part of the chalk district forms an elevated platform, and is considered as a type of the Vale of Pewsey. The northern part of the chalk is the site of a number of small hilly outcrops, known as the Downs or the Westwood, which are partly occupied by the Great Bedwin. The boundary of the chalk district is marked by a steep escarpment over the vale of Pewsey. The northern part of the chalk district forms an elevated platform, and is considered as a type of the Vale of Pewsey. The southern part of the chalk district forms an elevated platform, and is considered as a type of the Vale of Pewsey. The northern part of the chalk is the site of a number of small hilly outcrops, known as the Downs or the Westwood, which are partly occupied by the Great Bedwin. The boundary of the chalk district is marked by a steep escarpment over the vale of Pewsey.
Hill. A considerable part of this ridge and of the valley between it and the chalk hills is uncloisoned, if not uncultivated, and is very thinly peopled.

From Eddington the outer edge of the green-sand may be traced in an irregular line, marked by a clearly-defined escarpment, by Devizes and Potton to Market Lavington; then westward, but not with so clearly marked an escarpment, by Westbury to the border of Somersetshire, between Westbury and Shaftesbury. It forms the west side of the chalk between Warminster and Mere, the subjacent formations appearing only in one or two places to a very small extent. Between Mere and Wilton, and between this district and the Dorsetshire Stourhead, the green-sand is seen cropping out beneath the chalk, and occupies a very narrow strip of country, skirting the chalk district. About Warminster and Stourhead Park, in the south-western part of the county, the green-sand hills nearly equal those of the oolitic at the same period, near Aslockton, where it is on a green-sand hill 800 feet high. Ticklepath Hill, near Shaftesbury, is formed of green-sand.

From beneath the outer edge of the green-sand formation the Weald clay, or Tetsworth clay, which usually separates the green-sand from the iron-crops out. It occupies, only a narrow tract, surrounding on every side the country occupied by the superior formations, and may be traced through the county without interruption, except perhaps once, on the south side of the vale of Wardour, at the old iron-works near Bath, and at some other places, where the green-sand is covered by the green-sand. The outer edge of this clay formation runs by Swindon, Calne, Sandy Lane, Send (between Devizes and Westbury), and Dillon, into Somersetshire. In the vale of Wardour the clay occupies a very narrow strip, skirting the green-sand.

The iron-sand does not appear in this county, except in a few places, especially near the foot of Beacon-down Hill (chalk), between Calne and Devizes, rising toward Bowden Park, and at the Dorsetshire Stourhead, and is described as being a pudding-stone composed of rounded quartz united by a siliceous cement with a red calc of iron, containing ore formerly in much request for the furnace and the forge.

The absence of the iron-sand, the Weald clay is found to rest along its northern and north-western borders on the Kimmeridge clay, which belongs to the uppermost division of the oolitic group. This Kimmeridge clay occupies a tract rarely exceeding two miles in breadth, but extending in length from the Berkshire border to Swindon, beyond which it is covered by the westward extension of the overlying formations. At Swindon, in the Kimmeridge clay district, beds of oolitic freestone, similar to the Portland beds, intervene between the Weald clay and the Kimmeridge clay, and are described as being very clayey. In the vale of Wardour beds similar to the Purbeck beds (the uppermost in this upper division of the oolites) are found, and slabs are raised for roofing. Beneath the Purbeck beds the oolitic limestone crops out, and in the vale of Wardour, on the banks of Dunmore, the oolite crops out, and the chalk of the Chichester Hill. From beneath these formations a clay, which is probably identical with the Kimmeridge clay, crops out, and occupies the western part of the vale of Wardour, extending beyond the boundary of Wiltshire into Somersetshire. Much disturbed has been experienced by the denuded subcetaceous strata in the vale of Wardour. At Chicksgrove, on the banks of the Nadder, eight miles west of Wilton, they are horizontal; but at Chilmark, Fonthill, and Tisbury they are inclined 40°; and in the upper part of the county the upper oolites are confined to low ground; in the vale of Pewsey they acquire some elevation, as in Lady Down near Tisbury.

The formations already noticed occupy the whole of the county and extending westward to a line drawn south west from the Berkshire border, 3 miles south of Highworth, parallel to and a little to the north of the Wils and Berks Canal, by Stratton to the neighbourhood of Wootton-Bassett; and from thence south-west by west, across the canal by Calne and Bromham to Send; and from thence south-west to the Somersetshire border at Corley near Frome, the whole line making a circuit convex to the north-west. Beyond this boundary the strata of the middle oolites, comprehend the coral-rag and calcareous grit, and the Oxford clay, crops out, occupying all the northern border of the county and extending westward to a line drawn south west from Cirencester in Gloucestershire, by Kemble, Hankerton, Melmsbury, Stanton-St.-Quentin, Chippenham, Melksham, Semington, Trowbridge, and North Bradley, to Frome in Somersetshire; beyond which line the upper beds of the lowermost division of the oolites are observed.

The tract occupied by the middle oolites has a breadth of 8 miles along the northern part of the county, where it extends into Gloucestershire: between Wootton-Bassett and Cirencester it is 11 or 12 miles broad; and then diminishes south-westwards to the county line between Wilts and Somer- set, and Frome and it is probably not more than one or two miles broad. The lower or outer edge of the coral-rag and calcareous grit may be traced by a range of low hills and dales, in which this formation is observed, between Stroud and Frome, and to the eastward of Frome, near the civil parish of Wiltshire which is covered by the westward extension of the chalk and green-sand. The average height of the coral-rag hills seems to be about 400 feet above the level of the sea.

The Oxford or clunch clay occupies the lower green-sand beds, and is the border which subdivides the upper beds of the oolitic strata between the Kimmeridge and the green-sand. The limestone (Kelloway rock) which is occasionally found in connection with the Oxford clay, and which is used only for mending the road, has been observed in some parts of the county, such as the district between Cricklade and Melksham, and again about Melksham, Semington, and Trowbridge. Mineral-waters occur in this formation:

The formations belonging to the lower oolites in this county are the corn-brash, the forest marble, and clay; the clay occupies the entire area of the county, unless it is covered by other rocks, and is found in the northern counties, and in places near Calne, Devizes, and Stourbridge, and also at Melksham, where it is a thick clay, and is intersected by the river by the Cotswold range, appears to be chiefly composed of the great oolite; and their western slope is part occupied by the beds of corn-brash and forest marble.

Hydrography and Communications—This county is comprehended in the valley basin of the Thames, the Severn, and the Chichurch or Salisbury Avon; that part of the south-western border about Stourhead and Mere which is drained by the Dorsetshire Stour being included in the basin of the Avon, with which the Stour joins the Thames. The southernmost part of the county, which is included in the basin of the Thames, is so extensive that a line from the banks of the Severn to the banks of the Thames is about 20 miles. The county is included in the Avon above Melmsbury; but through the county near Tisbury, which is covered by the Cotswold range, appears to be chiefly composed of the great oolite; and their western slope is part occupied by the beds of corn-brash and forest marble.

Some of the streams which join the Thames in the upper part of its course rise in this county. One, which has been observed by some persons, but with very little reason, as the true Thames, rises just on the border of the county near Combe, and deriving its waters from the Cotswold range, crosses the Thames and Severn Canal by a Thames-head bridge, and flows south-east near Kemble, Somerton-Keynes, and Ashton-Keynes, a mile above which it is joined by the flagman brook from Oxford, and below which it is joined by the upper Lechlade, from which the river down below by the junction of the Swillbrook, it joins the Churn or true Thames (Taunton) from Cirencester, about a mile above Cricklade bridge.

The clay has a course of about nine miles before joining the true Thames (from Cricklade bridge), where the true Thames first touches the county, it flows four miles by Castle Eaton to the border of the county; then between three and four miles farther along the coast separating Wiltshire from Gloucestershire; and it joins the Severn near Lechlade. Between Cricklade and the border of the county it receives the key or Ray, and just above Lechlade the Cole, both which..
ise in the green-sand hills or in the northern escarpment of the northern chalk district, and joins the Thames on its north bank. The river (otherwise the River) rises in the green-sand hills near Wroughton, close to which village, within 2 miles of its source, it turns two miles; it runs northward, passing to the west of Swindon and close to the village of Water Eaton, its course, and by the course of about 10 miles; it receives several brooks by the way.

The Cole has three principal sources: one between Swindon and Chisledon, in the green-sand; one near Chisleh,

which also in the chalk-escarpment, and one in the chalk-escarpment. It flows northward, chiefly on the north side of Berkshire. It flows northward, chiefly on the north side of Berkshire. Its course through Berkshire is about 20 miles long; its course through Berkshire to its junction with the Thames at Reading is from 20 to 25 miles; making its whole length from 30 to 40 miles. Some small tributaries join the Kennet in Berkshire, 8 miles long. A tributary joins the Kennet on the chalk by Ogbourn-St.-Andrew and Ogbourn-St.-George, into the Kennet on the left bank below Marlborough; another, from Aldbourne, flows south-east and joins also on the left bank near Hambury, 3rd, rising in the chalk by Hambury, 3rd. A branch of Little Bedwin, joins the Kennet on the right bank near Hungerford; this last is partly incorporated with the Kennet and Avon Canal.

The Ton, sometimes called the Upper Avon, rises in the southern slope of the northern chalk district, in the neighbourhood of Devizes, and flows east-south-east along the vale of Pewsey by Beckington to Marden, Wivelisford, Charlton, and Rushall, near which village it divides into two branches. One branch flows first west-south-west, then south, along the vale of Pewsey, by Easton, Milton, Pewsey, Manningford-Abbots, Manningford-Bruce, and Newington. From the junction of the united stream flows southward by Upavon, Chisledon, Edington, and Drayton St. Martin into the Kennet. Milton, Bulford, Amesbury, Wilsford, Great Durnford, Woodford, and Stratford-under-the-Castle (i.e. the castle of Old Sarum) to Salisbury, at which it is joined on the right by the Wily (united with the Nadder): it is joined a little lower down on the left bank, by the Bourne, and still lower, on the right, by a stream which rises near Alvediston, and flows eastward through Ebbesborne-Wake, Fifield, Broadbalk, Stoke-Farthing, Plaistow, Bishopston, Toney-Stratford, to Stratfield-Lange-Bass, Hungerford, Oldbury, and Nunton. Below the junction of these streams the Avon flows southward by Standish house to Downton, a little below which it quits the county: its length from the neighbourhood of Devizes to the border to the county is 41 miles: its height above the sea is 215 feet. But that part of Christchurch is about 23 miles; making 66 miles in all.

The Wily or Willey rises in the downs north of Mere, in the south-west part of the county, and flows first east, then north by Kingston-Deverill, Monkton-Deverill, Brixton-Dev, and Badminton, for a short distance through Badminton, near which it bends to the east-south-east, then north, and past Bishoporton, Norton-Bavant, Heytesbury, Knook, Upton-Love, Boyton, Sherrington, Codford-St.-Peter, Codford-St.-Mary, Stourton, and Little Langford, to Stapleford. Here he joins on the left by a stream, 6 miles long, which rises near Odstock-St.-Mary and Orestock-St.-George, and passes Sherston, Maddington, Rolleston, Winterborne-Roke, and Berwick-St. James. From the junction of this stream the Wily flows south-east by Wilsford, South New- ton-Dorchester, Piggotters, then Millston, Manton, Bemerton, and West-Harnham, to Fisherton-Anger, a suburb of Salisbury, where it joins the Avon. Its whole course is about 27 miles. Near Quiddington it is joined on the right by the Nadder, which rises close to the Dorsetshire border near Devizes, and flows first east, then north-east by Donhead-St.-Andrew, and Donhead-St. Mary, to Tisbury; where it bends eastward and flows near Sutton-Mandeville, Fovant, Compton-Chamberlain, Bar- ford-St.-Martin, North-Burcombe, and Wilton, into the Wey: its whole length is by calculation 18 miles.

The Bourn flows just within the northern boundary of the southern chalk district, and flows southward by Colling- bourn-Kingston; Collingbourne-Duics, North Ridworth, South Ridworth, Shipston (these two villages are in a corner of Hampshire with the Bourn here crossed), Chold- erton, Newton-Toney, Allington, East-Boscombe, Idmiston, Ports, Winterbourn-Gunner, Winterbourn-Dansey, Win- terbourn-Ears, Winterbourn-Ford, and Laverstock, near Salisbury, below which it joins the Avon: its whole length is about 23 miles.

A very small part of the county about Mere, in the south-west corner, is drained by the upper waters of the Dorsetshire Stour, which rises at Stourhead in this county. The Avon and the Salisbury and the whole of their outfall into the English Channel at Christchurch.

That part of the county which belongs to the basin of the Severn is drained by the Bristol Avon, the source of which is in the Cotswold Hills, at Horton near Chippen-Sodbury and Dursley. The Severn is joined on the south side of Gloucestershire. The Severn, after crossing a circular course, 15 miles east, by Little Badminton, through Badminton Park, on leaving which it enters Wil- shire, by Luckington, Great Sherston, Easton-Grey, and Bretham or Cowage, to Malmesbury, where it is joined by a feeder from the river Frome. From Malmesbury the Avon flows in a winding channel 15 miles southward by Little Somerford, Great Somerford, Dansey, Selsey, Sutton-Benger, Christian-Malford, Kelmsco, and Tytherton-Lues, to Chippenham, which is only 10 miles by the road, and a distance of 20 miles in a winding channel south-west by Lay- cock, Melksham, Whaddon, Staverton, Bradford, and Limpley-Stoke, to the border of this county and Somerset- shire, between Bradford and Bath. Besides the few streams which joins it at Malmesbury, the Avon receives on the left bank a stream from Wootton-Basset, and the river Marden, a stream from near Devizes, and the rivers Wore and Frome. The stream from Wootton-Basset rises on the slope of the Avon near Bredon, and runs south-east by Bredon- Basset and Brinkworth, into the Avon at Dansey. The Marden rises in the green-sand hills (Compton Hill) above Compton-Basset, and flows by Calne, just below which it receives a stream (larger than the Marden itself), also in the green-sand hills. The stream flows north by the highway and Cliffe-Pypard, and which stream passes Hills- merton and Bemhill. The Marden is about 9 miles long; if measured from the head of the hill-marton branch it would be longer. The stream from the neighbourhood of Devizes rises east of that town, and passes near Stret- tern, Potten, and Semington: it is 13 miles long, and joins the Avon at Whaddon: it receives several feeders, two of them more immediately from the neighbourhood of Devizes. The Wore is formed by the junction of several streams which rise on the escarpment of the chalk downs about Westbury. The remotest spring is near Upton-Seadmore, between Westbury and Winterminister, and passes Dilton, Westbury-Leigh near Westbury, North Bradford, and Trobridge: the highest of the Wore rises near Winterborne, south of Westbury, chiefly to Somersetshire, but some part of its course (about Road, Tellisford, Farleigh, and Freshford, all in Somersetshire) is on the border of this county.

Of these numerous rivers only few are navigable, and that is the consequence of its central position and comparative elevation, from which it results that the principal streams have only the sources or the upper part of their courses in it. The navigation of the Kennet and the Wey begins as a matter of course: it does not commence until after those rivers have quitted the county. The Salisbury Avon was made navigable from that city to its mouth, under an act of 17 Charles II., but the works were destroyed by a flood soon after their completion, and remained in ruins until 1771. Some re-
pairs were then made, but they were inefficient; and the navigation is now given up except just at the mouth of the river; and even there the bar at Christchurch is an obstacle insurmountable except at spring-tides.

The want of river-navigation in Wiltshire is partially supplied by canals, of which three lines are connected with this county.

The northernmost line is that of the Thames and Severn Canal, which, in its course from the Thames at Lechlade in Gloucestershire, to the Stroudwater Canal at Stroud, is connected with the Severn at Castle Eaton and Cricklade. This canal was commenced under an act 23 George III. (A.D. 1783); and its formation led to the abandonment of the navigation of the Thames and Severn across the country by the border between Cricklade and Lechlade. The canal is not however so much used as was expected, partly owing to the inefficient navigation of the upper part of the Thames with which it is connected, and partly the paucity of traffic.

The second line is that of the Kennet and Avon Canal, which also connects the Thames with the Severn, by means of their respective tributaries the Kennet and the Bristol Avon. This canal is 97 miles long; it commences at the head of the navigation of the River Kennet at Marlborough in Wiltshire, and terminates in the river Avon at Bath: its rise from Newbury to the summit-level is 210 feet, effected by thirty-one locks; its fall from that level to Bath is 404 feet, effected by forty-eight locks. A considerable part of the navigation of the Kennet and the Bristol Avon is by means of canals; and its tributaries are three other - the Kennet at the northernmost, the Avon at the middle, and the Severn at the southernmost part.

The third line of canal-navigation is that of the Wilts and Berks Canal: it lies between the two lines already noticed (the Thames and Severn Canal, and the Kennet and Avon Canal), and connects the Thames near Abingdon, with the Kennet and Avon Canal at Semington, between Devizes and Bradford. Its whole length is 52 miles, with a rise of 108 feet from the Thames at Abingdon to the summit-level, and a fall of 201 feet from the summit-level to the Kennet and Avon Canal. After passing through the Vale of White Horse, in Berkshire, by Wantage (to which town there is a short branch), East Challow, West Challow, Uffington, Longcott (where there is another short branch) and Shrivenham, it enters Wiltshire, 21 miles from its commencement at Abingdon, and runs west-south-west along the valley at the foot of the green-and hills by Stratton-St.-Margaret’s, Swindon, and Wootton-Basset, through the village of Chippenham, where it turns south-west, and runs by Foxham, Tytherton-Luxona, Bremhill, Lacock, and Melksham, to Semington. The summit-level of the canal is in this county, commencing at Long Leaze near Boxton-St.-Martin. The section of the canal from Cricklade to Semington was formed as a separate canal under an act 53 George III. (A.D. 1813), and was called the North Wilts Canal; but has by a subsequent act (1 and 2 Geo IV., A.D. 1821) been connected with the Wilts and Berks Canal. It falls through the Wilts and Berks Canal at Semington, and near Wiltshire, having a fall of 50 feet, and passes through a short tunnel near Cricklade. There are two other branches of the Wilts and Berks Canal in Wiltshire: one of three and a half miles to Calne, with a rise of 21 feet; and one of nearly six miles to Marlborough, with a fall of 17 feet.

The principal coach roads are the present mail-road from London to Salisbury and Exeter, and the two former roads to Bath and Bristol. The Salisbury and Exeter road enters the county about two miles and a half beyond the hamlet of Bedwyn, and runs across Salisbury Plain by Winterlow Hat and St. Thomas’s bridge (over the Bourn) to Salisbury; and thence by Fisherton-Anger, Wilton, North Burcombe, Berford-St.-Martin, Compton-Chamberlain, Fovant, Berks, and Long Marshfield, to two miles and a half beyond which it quits the county.

The principal road is a mail-road which enters the county near Hungerford, and runs across several of the same forest to Marlborough, and thence across the former road to Bradford, Beckington, and Andover, until it reaches Cherhill, Blackland, Calne, Chipping, and Combe, to a mile and a half beyond which it quits the county. Other ex-mail-road branches from one to Devizes, Melksham, and Andover, runs past Pewsey, and turns into the Bradford road, to a point near which it unites with that through Calne and Chippenham. A third road to Bristol branches from the first of the two ex-mail-roads at Chippenham, and runs through Marshfield in Gloucestershire.

There are several roads from London to Exeter, beside the mail-road. One of these branching from the mail-road at Salisbury passes through Combe-Bissett, and enters Dorsetshire near Woodwaytes Inn. It passes through Broad-Charlton, Long Compton, and Bower, and runs from the mail-road at Andover enters the county at Fendalton, and runs across Salisbury Plain through Amesbury, Winterburn-Stoke, Deptford, Willy, Cricklade, and Men. Beyond which it enters Somersetshire. A road branching from this road to the Bristol road, between Styler Eolly, Muddington, Chiltem-Al-Saints, Chiltem-S. Mary, Newham, Heytesbury, and Maiden Bradley, beyond which it quits the county.

The road from London to Bristol via the Old Passage on the Severn is opposite the mouth of the Wye, branches from the Old road at Chippenham, and runs by Yatton-Kaye, Cadcombe, and Nettleton into Gloucestershire. Another road to the Old Passage enters the county at Colsclough in Ber. County. It passes through Highworth, the borough of Tetbury, Swindon, and Wootton-Basset, the Avon, Cricklade, Charlton, Malmsbury, Easton-Great Sherborne, and Luckington into Gloucestershire, uniting with the former road at Acton-Turville in Gloucestershire. A road branches from this road to Chippenham, and runs to Cirencester and Bradford on Avon. There are several roads from Salisbury, the county-town one runs south by west to Cranbourne, Wimbourn-Manor and Poole in Dorsetshire, branching from the road Exeter (through Bradford, Dorchester, and Honiton); one little beyond Corsham, through Wallop, and Wiltshire, and runs to Trowbridge. A road runs from Salisbury to Fordingbridge, Lyndhurst, and Christchurch in the New Forest in Hampshire: two south-east to Southampmore, one through Bradshaw, the other through Romsey: the one farther west to Winchester; one by Romsey, and one branching from the Leoudon and Exeter mail-road, through Stonehenge.
ridges: and two north-west to Bath and Bristol; one
through Chippenham, Westbury, Warminster, Westbury, and Bradford; the other running from this and Warminster, and joining
it at Bath.
The Great Western Railway has a considerable part of its
line in this county, which it crosses in a direction nearly east and west. It enters Wiltshire between the Shrivenham and Swindon stations, at
latter of which is 77 miles from the London terminus. There are stations at Swindon, Wooton-Basset, Chippenham
(95 miles), Gosham, and Box. There are two inclined planes here, one of which is attached to the Great Western Railway
branches from the Great Western at Swindon station, and aims, or is to run, to Gloucester and Cheltenham. It is
open as far as Gremister, including all the part which
belongs to this county. There are stations at Purton,
Usborne, and Gremister.

Agriculture.—In an agricultural point of view the
county of Wiltshire may be divided into two districts, the first
south-west, comprising all the Wiltshire Downs, with their intersecting valleys, and separated from the
Great Western by the chalk-hills from their entrance into the north-east part of
Berkshire to their south-west termination at Maiden
Bradley. We shall therefore consider these districts
separately.

South Wiltshire Agriculture.—South or more properly
South-East Wiltshire contains, in round numbers, about
500,000 acres of land. The Downs are an elevated table-
land intersected by valleys, which give the surface a broken
appearance. These valleys contain rivers and small
streams. The soil being generally more fertile there, and
the climate milder, cultivation was originally confined to
them; and there most of the villages are situated: the
higher and more exposed situations remain as natural pas-
tages.

The air on the Downs is keen, and healthy to robust con-
stitutions. The valleys, although more sheltered from the
sweeping winds from the Atlantic, partake of this keen
air, which is drawn along their course in currents.
The soil on the Downs varies little, being thin, and uni-
f ormly resting on the chalk. It produces excellent short
herbage, very well suited for sheep pasture; and where it
has been broken up, it is only by great skill and very care-
ful cultivation that it is made to repay the cost. It is com-
paratively free from weeds, and is admirably adapted to arable land, and chiefly on the borders of the valleys of
the cultivation but extends upwards in consequence of the
sand for corn offering temptations to the proprietors
of farmers to increase the quantity of land devoted to its
growing. The cloddy soil yields the best grass for
raising sheep on the arable land, and thus increasing its
utility. As we descend from the Downs into the valleys,
the soil generally becomes less mixed with flints and of a
peculiarity in nature, in consequence of the waters washing
up portions of the upper soil, of which the finer particles
are deposited on the sides of the hills, and form what is
called white land. The level part of the valleys nearest
the rivers consists of flints washed down lower, and mixed
up with the red gravel. The introduction of turnips and
beets, the cultivation of which is evidently owing to the stagnation of
waters in pools which have not had sufficient outlet; at
these spots are not numerous.

Some remarkable veins of sand intersect this district;
such as that of Great Western at Box, and a north and north-
that direction round the outer edge of the Downs, keeping
together closely to their foot, by way of Maiden Bradley, War-
somer, Westbury, and Lavington, towards Devizes, where
beaux are common, and the steep hillside between the river and the
 Pennen down the Pewsey vale from Burbage. Another
 vein also enters the county from Dorsetshire, being a con-
nexion of the sand-hills on which Shefford-down stands, and
washes through Donhead, Ashey, Swallowcliff, Foxley, Scor-
ton, and on to its junction with the broad down in Somersetfield.
This vein is also met with near
Fovant by another branch, or rather a ridge of sand-hills,
coming from West Knoyle by Stop-Seaton and Ridge-

These are the principal soils in this division; and although
there are some spots of a more clayey nature, they are not
extensive. See the Report to the Board of Agriculture,
by Thomas Davies.

The system of cultivation was originally such as the
nature of the more fertile soils and their connection with
the Downs suggested. The principal produce; and no more
was grown than the necessity of the inhabitants
required. The estates or manors extended in narrow strips
along the valleys, and had certain rights of common
and pasture attached to them. These were let partly
commonly subdivided, and the arable land lay in common
fields, in divisions and patches, which precluded any system
of cultivation which was not adapted by general consent.
This is the history of all common fields. Folding sheep on
the downs was the great resource; and the numerous streams
suggested artificial irrigation, by which hay was increased
for winter-feed and early grass for the lambing season.
In no part of England, as we shall see hereafter, was the
system of water-meadows introduced so early or carried to
perfection. In fact, it was one of the chief
features of the agriculture. A farm consisted of certain
buildings and homesteads, with meadows, irrigated if pos-
sible, or kept in heart by folding; with some fields to raise
corn for the family, and a run on the Downs for a certain
profit. Since the common fields have mostly been en-
closed and divided among the proprietors, more land has
been cultivated and better systems adopted; but this has
not altered the methods of farming, or the certain sanctity in the eyes of the farmers, who were more used to bring it from what they have seen their fathers
do before them. A great and gradual improvement however
has taken place, and new methods are daily intro-
duced. For a time it was common to grow winter
while the rents were improved; and it will in the end render this part of the country
far more important in an agricultural point of view than it is now.

The buildings on a farm were formerly very extensive,
and occasioned a great expense to the proprietors in con-
gen and repair. Since the introduction of the
method of stacking corn out of doors, which is so much better and
more economical than laying it up in barns, and especially
the introduction of threshing machines, the buildings are
now much contracted, and a less burden to the proprietor,
and better in a general way. Lime is still a principal object of the Wiltshire farmer; but his
attention is not confined to them, and he makes them sub-
ervant to a greater production of corn.

By the old system the sheep ran on the commons or Downs
during summer and autumn; and in winter the summer flocks
till they were ploughed up for wheat: as soon as the corn
was reaped, the flocks had the stubbles and the Downs to run
on, till winter forced the owners to give them hay, when
the farmer found his fold and hay, the common sheep
were still feeding and folding the extensive land and the
farmer had his own shepherd and folded on his own land.
When the ewes are near yeaning, the owner takes them
to the enclosed meadows, and by the time all the
lamb are dropped the water-meadows are ready to receive
them. As there is seldom sufficient food in winter for the
whole flock, a portion is necessarily sold off in autumn to
supply other counties, where they have more winter forage.

The greatest change is seen in the purchasing power of the
system; many of the wethers and barren ewes are
fatted at home, and the only portion sold off are the
lambs and tegets, which have been bred for this
purpose, without diminishing the breeding flock.

These flocks were formerly much larger than they are at present, but it has been found that the expense of
men and horses on a small farm is much greater in proportion
than on a larger. It is most advantageous to the farmer who
has the largest flock which one shepherd can manage to
have two or three flocks, and to keep as much arable land as will fully occupy one horse. Little
as can be profitably farmed: many
which is in the hands of a farmer, or the labour of a farmer who has the power of
ensuring good work at each department. The farmer
met with the employment of the arable land
as the condition of common flocks, and especially two crops and a fallow, valued by a
fourth of

grass-seeds, which could be

wax jujubae, and by a

Digitalized by Google
sent to waive the right of common pasture after hay-making. Since the enclosures the system is improved; turnips are raised in considerable quantities, their use for winter-feed having been soon found out. Clover, vetches, and other artificial grasses come into the rotation, and the only fault in the different systems is that which is yet too often met with, of two white straw crops following one another; the only palliation of this is the abundant folding of sheep on the downs, which keeps it in heart and prevents its exhaustion.

The Wiltshire ploughs are mostly without wheels or with only one wheel; the former are used on rough heavy soils, and the latter on light light and stubble lands; on these soils a plough with two wheels is generally used, as being steadier; the furrows being necessarily shallow, the swing-plough would be too easily thrown out of the ground. The heavy white lands require three horses at least to a plough, and but they can be easily ploughed with two; and, with good ploughmen, light ploughs might be used, such as the improved Berkshire and Suffolk ploughs. The carts and wagons are too heavy. A light single-horse cart is far preferable, and will do better be generally attempted when the market is good. The short light thin soams on the Downs, when cultivated, require much skill to make them productive. Formerly they were much worked and pulverized in summer, by which the texture was too much loosened, and the surface made extremely greasy. The wheat was sown well in spring; but the earth was blown away from the roots in high winds and dry weather, and abundant crops of poppies took the place of the thin and withered corn. This may be the farmers have adopted a better plan; the idea to give firmness to the folding, before sowing, and the crops are much improved.

The common practice of raftering the land, as it is called, that is, ploughing a furrow and laying the furrow-slice on the solid land, and then opening another furrow 18 inches from the first, so as to produce another similar ridge, leaving the surface in alternate open furrows and double ridges, has the effect of killing the grass and exposing half the roots to the air, the other half not being stirred. When this is done annually together and diagonally, with better, one harrowing down and ploughing prepare the land for wheat sowing; and the crops justify the practice, but it is faulty in that it soon fills the land with weeds. One good ploughing and pressing with iron cylinders after a clean layer is a far better preparation. A heavy dray or a nine-a-side plough is very commonly used as a substitute for ploughing. It stirs and cleans the land at the same time, raising the root-weeds to the surface, to be gathered and burned. In the sandy soils the seed is generally deposited by the manure-machine; but where flints abound this implement is not so applicable, and the broad-cast sowing is continued.

The most common rotation now adopted on the heavy white lands, where turnips will not grow, is that of fallow, wheat and barley, clover mown, ditto fed, wheat, beans, or oats. The second year of the clover it is broken up early in summer and well pulverized, and the sheep are folded on it at night; the wheat is generally good after it. Half the barley or wheat stubble is now generally sown with peas, beans, or vetches, and the other half with clover; the land is kept clean by weeding and hoeing the crops, and the clover is more certain from not recurring so often.

On the Norfolk common land, barley, clover, wheat, is commonly adopted, with the variation of a fallow between the clover and wheat, when the land is close folded and thus consolidated. Some good farmers have peas or vetches fed off early on half the barley land, to prevent withered and frequent re-treadings of clover; these are flints, but the sandy loam is so nearly allied to clay as to be cropped like heavy land, and the crops here are more certain and abundant. The Down land is cropped in various manners, turnips and barley or oats being the principal crops; on the deeper redd soils wheat is introduced every fourth or fifth year. Rape and rye-grass are sometimes sown together after wheat, to be fed off in spring, and the grass is continued a year or two more to recruit the land. The flocks of sheep which are kept everywhere give the principal supply of manuring by the fold; as fewer horned cattle are kept in the years. When the ewes and lambs feed in the water-meadows, the folding is found to be far more effective than at any other time. This is probably from the abundance of unripe produce by the fresh succulent grass.

Potatoes are raised in considerable quantities on the rich sands, which are peculiarly adapted to this crop; and it has been a common observation, that a bad year for what is generally a good one for potatoes, which increases the value of this excellent root.

We are alluded to the water-meadows, which is this part of the county are extremely well managed. There are two kinds of water-meadows, those irrigated by art work and which are flooded. [Ignoramus.] These water-meadows are made by flooding the lands lying along the rivers or rivulets, and are flat and level naturally or rendered so by art. The water is let on by sluices and channels from the upper part of the stream, and kept in by banks, if necessary, and let off again into the lower part of the stream. The better meadows can be easily ploughed, and will make excellent ploughs. This method requires a greater supply of water and more expensive works. The expense is often from 10l. to 20l. per acre; but the return is so large, that this is a capital extremely well laid out. It is computed that 20,000 acres of excellent water-meadows in this district.

As soon as the after-grass is eaten bare in autumn, the water is let on; all the grips and channels which may have been damaged by the treading of the cattle being repaired. The wheat is sown in May or June, the operations for this season is soon after Michaelmas, when the rains being fine from the hills around. The water generally covers the meadows for a fortnight or three weeks, to give them a good soaking at first, and to make them close and firm by pressure and weight of the grasses. It is then let off till the surface is quite dry again. If any seeps appear on the water during the flooding, it is immediately let off, or it would do harm. When the growth of the grass seems to flag, the water is let off, and they are mowed only. During hard frost it is useful to have all the meadows covered with water, which prevents the first touching of the roots; as spring advances the flooding must be much shorter, till the grass attains the proper size and condition. If at any time the water fails to flood a meadow, or if it lies on a declivity, the catch-work is the only method applicable, and the let on and off of the water is regulated on the same principle. The great value of early and abundant grass for cows and both makes these meadows of the greatest consequence to the sheep-farmer. When they are fed off close, by the end of April or later, the water is let on for a day or two and then let off. In six weeks after a very heavy crop of hay may be made; another short flooding produced this result. A small water-meadow on the Cherchon, six miles from Amesbury, which is usually called the 'long grass meadow.' They contain together only 24 acres; but the crop of hay is sometimes so enormous, that the tithe of it was once sold for five gill. It is found that the crop of one of these, Agrostis Stolonifera is by far the most abundant, in fact almost excluding all other grasses. This is the Florin grass, once so strongly recommended by Dr. Richardson as to cause universal notice amongst agriculturists; but they do not always produce this remarkable result in all cases. Its celebrity had a short run. As the rivulet which supplies the water to these meadows is subject to great variations in different seasons, and sometimes is low in winter, it happens then that very little hay can be cut in summer; but this is not often the case.

As the cows in this district are not such objects of attention as the sheep, the breeders are very various, and few of them of superior quality. The chief dairy is the Jersey, to the breed used in the towns, North Wilton, producing little butter, except whey-butter—its chief produce being cheese.

The Wiltshire sheep are a variety of the Southdown,
but not in general so pure. The original breed was horned, but this has been almost entirely superseded by the polled breed, which produces a finer wool, though not so large a carcass. Of late the size has been an object to the breeder, since fine wool has much diminished in value. An attempt was made in the middle of the last century to cross the English crosses between it and the Southdown, but it did not answer: the sheep were too delicate for the climate and feed, and the superior quality of their wool did not make up for the inferiority of the carcasses. There is probably at this moment not a remnant of Merino blood in any flock in Wiltshire.

The great object in keeping a flock of sheep formerly was to fold them, and for this purpose they must be strong and coarse; where the early ration is the principal object, and a different breed of sheep are required. The Southdown breed was introduced into Wiltshire in 1788, by Mr. Mitchell of Kennebec, and since that time has almost entirely superseded the old Wiltshire breed. Crosses with other flocks through the Merino and the Leicester, to now very common; and since the carcass has become the chief object, these half-breds, as they are called, are thought by some to be most profitable. Their wool is not so fine, but longer, and the fleece heavier.

Large towns have also the same effect on the same as in other counties; the Chinese and Neapolitan breeds having by their crosses improved the original breeds and altered all their qualities, they are reduced in size and bone, and fatten both earlier and in less time: all these things have opened the eyes of the farmers; for many reasons, the advantage of a smaller size has been so readily recognised in the pig, many breeders still aim at the same size in the horse and ox. Experience will perhaps convince them, in the end, that they are wrong, and that, generally speaking, a small animal of perfect symmetry is more profitable than a large one.

North Wiltshire Agriculture.—The north-western district of Wiltshire differs greatly from the southern district. The subsoil in this part of the county, instead of being clayey, consists of a bed of boulders and rubble, generally corn-grate. It is the same as that of the Cotswold Hills in Gloucestershire. These stones serve for building when they are of sufficient thickness, and the thinner layers to cover houses, instead of slate. The top soil is a reddish calcareous loam mixed with irregular flat stones, and commonly called stone-brash. In some places a stratum of clay is interposed between the rock and the top soil, which may easily be known by the oaks which thrive there. These piggots are much the same as in other places, and the subsoil common in the northern parts, with great advantage of a smaller size has been so readily recognised in the pig, many breeders still aim at the same size in the horse and ox. Experience will perhaps convince them, in the end, that they are wrong, and that, generally speaking, a small animal of perfect symmetry is more profitable than a large one.

There is a very fertile vein of gravel, or rather of small shelly-sand with pebbles, covered with a good depth of rich mould, which runs in a broken line from Melksham through Chippenham to Cricklade, but extends wider from Tisbury through the western and northern parts of Wiltshire, and into Somerset. All this vein is very rich land, especially near Downtrey. The porous subsoil keeps the soil dry and warm better than any artificial drainage could do. A less fertile vein of sand runs from Redburn by Seagry, Draycott, and Southwick through Chippenham to Langley, and another begins at the opposite corresponding hill at Charlton, and runs through Bremhill to Branhall. The greatest part of the residue of the soil of this district lies on a rock face of a rough irregular cliff, and is not good till it is relieved by the natural grass, and the grass is of the wild or rough kind: the soil above this rock is mostly retentive of moisture, and consequently cold. Bradon Forest consists of a poor iron-clay fit only for wood, and notoriously ungrateful to the cultivator.

In this district there are a dozen or more of districts, each with distinct characteristics, and probably so from times immemorial. The buildings are well suited to this purpose, and placed conveniently with respect to the surrounding fields. The cheese-lofts are often on a very extensive scale; and all the buildings are kept in a neat and substantial order. Leases are common for 14 or 21 years, and the tenant is prevented from selling hay or straw, which secures his keeping sufficient stock for manure. The implements are similar to those used in the southeastern district. The common fields have been mostly enclosed by acts of parliament, to the great advantage of the

husbandry. Some of the best land has been laid down in grass, and a better system of cropping has been generally introduced, and a cleaner tillage.

The most common rotation in the beginning of this century was that of wheat, oats, turnips, barley, clover mown, then fed, and summer-sown; but the fact is, wheat was not a bad course, but improvements have been introduced according as the soil was heavier or lighter. Folding sheep on wet cold clays is never profitable, and feeding oxen on oil-cakes and hay has only been introduced of late years, and by no means generally. On the lighter soils, barley does not come to such perfection in the heavier soils, which are better adapted to beans and vetches as a preparation for wheat, instead of a too frequent recurrence of clover. The turnips after wheat and oats, with only the sheep-fold to retentive, is not necessary, as the feeding of turnips and fresh grass, and the feeding of sheep on the turnips does not sufficiently enrich it when the crop is light. Most of the cold clays require draining, an improvement of which the farmers are so striking, that it must soon become very general on such soils.

The grass land forms the greater portion of North Wiltshire, and the cheese made there is justly celebrated. It is mostly bought up by factors for the supply of London and the surrounding market; and a large number of dairymen now keep their cows in the stalls from November to April, as they do in Holland. They find the advantage of this practice both to the cows and the pastures; and this art gives them manure for the arable land, as well as the grass land, which is more improved by manuring with rich compost than by the irregular droppings of the dung from the cows in the pastures. The manuring of grass land is generally done immediately after hay-making. This improves the system, and the dairying land and pasture, large land alternately, have done much good to the pastures, and kept them free from docks, thistles, and other weedy.

Much of the heavy wet soils has been improved by under-draining, but a great deal remains to be done. The pastures in the southern part of the county have been adapted to hay-making, but those in the north and west, and if these are only made sufficiently near to each other, the nature of the soil will soon be altered for the better, where it is too wet and cold.

Considering the extent and perfection of the water-meadows in the southern district, it is surprising that there are so few in the northern. This must be ascribed to the difference in the systems pursued on sheep-farms and dairy-farms. There is not the same necessity for a rich food for calves in spring; and upland dairy land is preferred by many to lowland meadow hay; yet the advantage of water-meadows for cows, as well as sheep, should have drawn more attention to their formation.

The breed of milch-cows is an object of greater attention in this part of the county than in the south in general. This breed was formerly in high repute, as the old cows fattet well and produced good prices from their weight. Each cow of the large breed will give from 3 to 4½ cwt. of cheese in a season, if she calves in proper time. But if more cows are fed on the same land, they will adapt the grass in every acre produce more cheese, whatever each cow may give, the smaller cow is evidently the most profitable; besides, smaller animals require less food, and will thrive where the larger would fall off. It will probably be found, in the end, that good breeds of small cattle are the most profitable. The best are the Astray cows and the small Suffolk polled breed. The North Devon are sometimes excellent milkers, and they certainly are the handsomest breed. A great many cows are fattet in the dairies, when they are dry or have missed calving.
There are very few market-gardens or orchards in this district, and no cider is made. Vegetables are only raised for sale near the towns; every farm having as much garden as the family requires, and no more. The woods have diminished greatly all over the county, which was once very well wooded; and the fuel and wood from coal, the decay of the woods begins to feel. If plantations were judiciously made, there is no doubt but they would ultimately pay well. Much of the land is peculiarly suited to the growth of timber and uncultivated.

The sheep in this district are mostly the same as in the southern portion of the county, and although there are not so extensive sheep-pastures, there is usually a flock attached to every arable farm, and folding is one of the chief modes of cattle. On the fields, cattle fattened in yards would probably produce manure of a better quality for turnips, and would be more economically fattened than sheep, for which there is not always sufficient feed at all times of the year for want of water-meadows.

Many pokers are fitted in the dairies on the whey, after it has been skimmed and whey-butter made, and the breed of pigs has been much improved of late by judicious crossing with small-boned breeds, which fatten earlier and in less time. There is nothing peculiar in the breed of hogs consumed on the farms, are mostly imported young from other counties.

There are many excellent markets in Wiltshire; the principal corn-markets are Warminster, Devizes, and Salisbury. Swindon and Salisbury are the best for cattle-markets. Marlborough is a great market for cheese, although most of it is contracted for by factors, who take the whole produce to London, Bath, and Bristol.

The principal fairs in Wiltshire are:—Amebury, May 17, June 7, July 7, and Oct. 2; Bradford, Trinity Monday; Bridgford, Aug. 12; Calne, May 6, Sept. 22; Chippenham, May 17, June 22, Oct. 29, Dec. 17; Corsham, Holy Thursday; Whitchurch, second Thursday in April, Sept. 21; Devizes, Feb. 13, April 20, Holy Thursday, July 5, Oct. 2, and Christmas; London, Easter Monday, Sept. 24; Downside, April 23, Oct. 2; East Lavington, Aug. 10; Great Bedwyn, April 23, July 26; Heytesbury, May 14, Sept. 25; Highworth, Aug. 13, Oct. 11, 29; Hindon, Monday before Whitsunday, Oct. 29; King’s Down, Wednesday before St. Matthew’s day; Liddesdale, July 25; Marden, June 5, Oct. 2; Melksham, March 28, April 28, June 6; Marlborough, July 10, Aug. 22, Nov. 6; Melksham, July 27; Mere, May 17, Oct. 10; Norcester, April 23; Purton, Tuesday before May 0, Thursday Easter; Redvers, May 14, Oct. 2, and Christmas; Salisbury, Tuesday after Jan. 6, Whit Monday and Tuesday; Tisbury, Monday before Easter, May 2, second Monday after May 12, Sept. 11, second Monday in Dec.; Tidworth, Aug. 5; Trowbridge, April 23, Sept. 22, Oct. 29; Warminster, May 1, Nov. 17; Westwood, Easter Monday; Whit Monday; Whorwell, Nov. 17; Wilton, May 4, Sept. 12; Wootton-Basset, May 4, Nov. 13, Dec. 19; Yeovil, Oct. 4.

Divisions. This county is divided into twenty-eight hundreds, which, with their respective positions in the county, areas, and population in 1831, are as follows:

The city of Salisbury is included in Underditch hundred, the borough of Devizes in Poterne and Canings hundred, and the borough of Marlborough in Selker hundred.

Wiltshire contains the county-town and city of New Sarum, or Salisbury; the parliamentary borough of Calne, Chippenham, Cricklade, Devizes, Melksham, Marlborough, Westbury, and Wilton; the disenchanted borough of Old Down, Downside, Heytesbury, Malmsbury, Malmesbury, Selkirk, Old Sarum, and Wotton-Basset; and the market-towns of Amesbury, Great Bradford, Corsham, Highworth, East or Market Lavington, Melksham, Mere, Selkirk, Trowbridge, and Warminster. Some of these places are described in separate articles:—[AMEBURY; BATH (GREAT); CALNE; CHIPPENHAM; CRICKLADE; DEVIZES; SALISBURY; SARUM.] Of the rest we subjoin an account.

Malmsbury is in the hundred of Malmsbury, 10 miles from the General Post-Office, London, by the Great Western and by the Midland Counties Railway. It is 8 miles from Devizes, 24 miles from Swindon, and 12 miles from Highworth. According to an anonymous history of Malmsbury priory, compiled in the mid-fourteenth century, and quoted by Leland in his Collectanea, there was a town here with a castle, reputed to have been built by Bo- wallo Malmutiu, one of the Britons kings to have resisted the Roman invasion. The town was afterwards destroyed by foreign invaders, but the castle remained, and near its walls a Scottish monk, called Maidelph or Meldalp, who had been so worried in his own country as to escape hither, were reared for the Danish invaders of the ninth and tenth centuries. In the twelfth century, the town was twice burnt; but it recovered, and being enriched by lands and crowned venerable by relics, became one of the most important monasteries in the north of England. This abbey, built by Prince Harold, after the battle of Stamford Bridge, and had the residence of kings both pagan and Christian, but without distinguishing whether Saxon or Saxon. This partly fabulous narrative may perhaps indicate that there were at Malmsbury at a very select period a castle and a town. Maidelph founded his monastery in the seventh century, and from him the modern name Malmsbury, a corruption of Maidelphsburh, appears to have originated. It is probable that the abbey suffered from the Danish invasions of the ninth and tenth centuries when the town was twice burnt; but it recovered, and being enriched by lands and so venerable by relics, became one of the most important monasteries in the north of England. The abbey was at first dedicated to St. Mary, and was afterwards dedicated to St. John the Baptist. The yearly revenues of the abbey at the dissolution were 803L. 17s. 7d. The town appears to have had a charter as early as the reign of Athelstan, when the inhabitants are said to have been granted the right to hold a market. In the reign of Stephen a castle was built here, and the town was walled by Roger, bishop of Sarum, who was however obliged to surrender the castle to the king. In the civil war of Stephen and Maud, the town and castle were taken by the Danes, and held by Prince Harold, after the battle of Stamford Bridge, and was afterwards held by Prince Harold. In the civil war of Charles I., the royalists had a garrison here, which was driven out by Sir William Waller, at the head of a parliamentary army, March 1643. The royalists recovered the place, but it was again
taken by the parliamentarians under Colonel Massey, or Massie, who stormed it, a.d. 1645. The cloth-trade flourished in the middle ages, according to the testimony of Leiland, who says that 3000 'clothes' (pieces of cloth) were made yearly. These buildings were converted into a cloth-factory by one Stumpa, a clothier, to whom the king had granted them.

The town stands on an eminence in the middle of land formed by the junction of the Avon and the stream (Le-

land, if not the Newtonwater). There are two

borough, and consists of some streets irregularly laid out,

but paved and lighted. The town does not extend much

beyond the limits of the municipal and old parliamentary

borough, which comprehends the abbey parish or district,

and county and all the parishes. The chief object of this

report; the chief part of these parishes is without the bo-

weight limits, but the population returns do not discrimi-

nate between the in-parts and out-parts. The statistics of

the three parishes, in 1831, were as follows:

Of the population 2334 persons were comprehended in
the old borough. By the Boundary Act several adjacent
parishes were added to the borough for parliamentary pur-

poses, enlarging the population to 6165. There are two

churches—the Abbey church and St. Mary's, and the

remains of a third—old St. Paul's. The Abbey church

was, at the dissolution, purchased by the inhabitants of St.

Paul's parish, and made parochial. It is well described

in Leiland's Itinerary; it was the seat of the Westover

cross-church; the central tower had fallen before Lo-

land's time, and now but a small part of the church re-

 mains, that is to say, part of the nave and aisles, the

grand southern porch, and a wall belonging to the south

nave. The upper part of the western tower, which

was standing in Leiland's time, has since fallen, and the part

of the nave immediately adjacent to it is dilapidated, so that

the part now used stands in the midst of ruins. The ar-

chitectural work of remains the west front and the ad-

jacent parts are decayed; and it is not improbable

which is beautifully enriched, is Norman; the rest of the

nave appears to be chiefly of decorated English charac-

ter. The interior is a mixture of the Norman and the

English or pointed style. In the interior, near the altar,

is a large altarpiece of architectonic fragments, inclosing a

space in which stands an altar-tomb, with an effigy in

royal robes, said to represent King Athel-

stan, who was buried in the church of Malmesbury Abbey;

the tomb is however of much later date than that prince;

and is now far from the place of his interment, which was

in the choir, under the high altar. There were formerly

three churches in the churchyard of the Abbey; namely,

the Abbey church just noticed; the old parish church of St.

Paul's, of which the lofty tower is still standing; and an

old abbey or church of the same name, which was used as

a belfry, while the church itself, now completely destroyed

from the tower, is occupied as a dwelling-house; and a

little church, which Leiland describes as 'a very old piece

of work,' used in his time as a cloth-factory, and now alto-

gether destroyed. The church of the abbey, now the Westover

mean-looking building, erected nearly two centuries ago

on the site of the old church, which was destroyed by Sir

William Waller. There is near the Abbey church a house,

the lower part of which was probably part of the abb's

hall. It is a more sumptuous and ancient cross in the market-place, which

Leiland records as having been built within the memory of men; and west

of the Abbey is a building called Chapel-house, supposed to

have been originally the chapel of a nunnery which

Leiland has preserved notice of, or traditions of two other nunneries in or near the town.

The White Lion Inn is thought to have incorporated in it

some remains of an hospital or house of entertainment

belonging to the abbey; and the corporation almshouse,

near one of the bridges over the Avon, is supposed to

comprehend some remnants of an establishment of the

Knights Hospitallers. There are some fragments of the
town walls.

There are several dissenting places of worship, and four

houses—two over the Avon and two over the Newton-

water. Malmesbury has little trade or manufactures: the

clothing trade gives employment to a few persons, and

ware, brewing, and lace-making are carried on. The

market returns on Saturday, and there were a large cattle-

markets or fairs for horses, cattle, and sheep.

The borough has returned members to Parliament with

little interruption since the time of Edward I. By the

Reform Act it was reduced from returning two members and one

return only one member. By the Boundary Act the limits

and population of the borough were much enlarged. It

is not noticed in the Municipal Corporations Reform Act.

The living of St. Paul's is a vicarage, united with the

parochial curacy of St. Peter's, which is in the parish of St.

Paul's, and is in the joint clear yearly value of

265s., in the rural deanery of Malmesbury, in the

archdroncy of Bristol, in the diocese of Gloucester

and Bristol. The living of St. Mary Westport is a vicarage,

united with the adjacent parochial churches of

Borough and Charlton, jointly the clear yearly value of

310s., in the same ecclesiastical divisions as St. Paul's.

The parish of St. Paul's and the abbey district com-

prehended, in 1831, eight day-schoools of all kinds, with

265 scholars, namely, six boys and 49 girls; two other

than one in eleven of the population under daily instruction.

One of these day-schoools was an endowed school, with

15 boys; two were national schools, with 60 boys and

45 girls. The national schools were attended on Sundays

by 70 boys and 47 girls, and on school-days by 500

boys, with 405 scholars; giving 520 scholars, or above

two in nine of the population, under instruction on

Sundays. There was no return made from the parish of St.

Mary Westport.

Three writers of eminence in their respective ages

connected with Malmesbury:—St. Aldhelm, a Saxon

writer of note in the seventh and eighth centuries, was for a

time abbot of Malmesbury, where he was interred; William

of Malmesbury, one of the best English historians of the

middle ages, was a monk of the abbey; and Thomas

Hobbes, sometimes designated the Philosopher of

Malmesbury, was a native of the parish of St. Mary Westport.

Marbleford is in Selkirk hundred, 734 miles from the

General Post-office, London, by the General Western Rail-

way, and 3 miles from the Nursery of Newbury and

Hungerford. Some antiquaries have pro-

posed to fix the Roman station Cunetio, of Antoninus,

at Folly Farm, close to Marbleford; and the evidence in

favour of this opinion is strong. There is a bowl

Marleborough in the time of Richard I., which was

seized during his imprisonment by his brother John; but

on Richard's return it was reduced under the king's

power. A parliament or assembly was held here in the

time of Henry III., the provisions in which are called

the Statutes of Marlbridge, one of the older forms of the

name, which in Domesday is written Marliberge.

The site of the castle is covered by a large house, which was a seat

of the dukes of Somerset, and was afterwards used as the

garrison of the army. Within the last year it has been

fitted up as a Clergy School, and has been opened with

good prospect of success. The mound of the antient keep

is in the garden. The municipal and old parliamentary

borough comprehends the two parishes of St. Mary

and St. Peter; the statistics of which in 1831 were as follows:

<table>

The parish of Presbute or Manton was added by the

Boundary Act for parliamentary purposes, and enlarged

the population to 4196 persons.

The town of Marlborough consists chiefly of one wide

street running from east to west, and lined with houses, irre-

gularly built, and many of them old. Most of the houses are of brick. The streets are roughly paved on each side with large stones or pebbles taken from the downs adjacent. The market-house for cheese, butter, and corn, is at the east end of the street: it is an antient building, having in its upper story a council-chamber, assembly-rooms, and committee-room, where a committee of the drapers' market assembled near it. The churches are both in the main street, with St. Mary's at its eastern end, near the market-house; it is an old church with a freestone tower at the west end, with a Norman doorway enriched with zigzag ornament: the church is dedicated to St. Peter and St. Paul. There is a church near the street, adjacent to the Castle Inn, and has a lofty square tower with battlements and pinnacles. There are, on the south side of the street, some remains, now converted into a private house, of an antient priory for the regular Canons of St. Augustine. There are several Dissenting places of worship in the town.

The trade of Marlborough is not great; it is chiefly in coal, corn, and malt. Before the opening of the Great Western Railway, it was a great thoroughfare, and one of the chief posting towns between London and Bath and Bristol. There is a small market on Wednesday, and a more important one on Saturday; and several yearly fairs. Marlborough is a borough by prescription; the corporation, under the Municipal Corporations Reform Act, has four aldermen and twenty-one councillors, with no commutation of the franchise or peace. It sends two members to parliament; its boundaries were enlarged by the Boundary Act. The living of St. Mary's is a vicarage of the clear yearly value of 100L. with a glebe-house; that of St. Peter and St. Paul is a rectory of the clear yearly value of 130L.; both are in the rural deanery of Marlborough, in the archdeaconry of Wilts, and the diocese of Salisbury. There were in the borough, in 1833, twelve day-schools of all kinds, with 531 scholars, namely, about 200 boys, 236 girls, and 93 children of sex not distinguished in the return; giving between one in six and one in seven of the population under daily instruction. One of the day-schools was a small but well-endowed grammar-school; and one, a national-school, with 67 boys and 65 girls. On Sunday-schools. There were besides two Sunday-schools with 117 boys and 154 girls; giving in all 433 children, or one in eight of the population, under instruction on Sunday.

Henry of Marlborough, an historical writer of the fourteenth and fifteenth centuries; Obadiah Sedgewick and Christopher Fowler, eminent puritan divines of the seventeenth century; John Hughes, the poet and dramatist; Harte, the historian of Gervasius Adolphus; and the well known Dr. Sacheverell, were all natives of Marlborough. Wilton, on the western side, 102 miles W.S.W. from the General Post-Office, London, by the South-Western Railway to Basingstoke, and from thence by Andover, Ludgershall, Rushall, and Market Lavington. It is a place of considerable antiquity, and a number of Roman coins have been cleared up in the vicinity, and one ancient coyness have proposed to fix here the site of the Antonine station Verucio, but the opinion is not general. Little is known of the antient condition or history of Westbury: it was incorporated by Edward I. by charter, and sent members to parliament in the time of Henry VI. The statistics of the parish in 1831 were as follows:—

The old borough comprehends only a part of the town; it was augmented by the Boundary Act by the addition of the other parts of the parish. The town consists of one long crooked street and of some smaller streets, irregularly laid out. The church of St. Mary, Leigh forms another street, separated by an interval of open road from the principal street. The church is a large antient building, with a central tower and a fine west window, and several monuments. A handsome town-hall was erected, a.d. 1815, by Sir John Thynne, the then proprietor of the borough. The clothing manufacture is carried on in the parish, though not to the same extent as formerly; it gave employment in the whole parish, in 1831, to 200 men, besides women and children. The market is on Friday, and there are two considerables yearly fairs for cattle, horses, pigs, sheep, and cheese.

The borough was formerly very close: the corporation is not noticed in the Municipal Corporations Reform Act. The living of Westbury is a vicarage united with the chapelry of Dilton and Bratton, of the joint clear yearly value of 200L., with a glebe-house, in the rural deanery of Wiltshire, in the archdeaconry and diocese of Salisbury, but in the peculiar jurisdiction of the precentor of Salisbury cathedral. The parish of Westbury contained in 1831 1,558 souls, in 314 houses, of which 787 were inhabited, with 753 persons, in 277 houses, being the inhabitants of the town, and 521 persons, in 361 houses, being the inhabitants of the country. The population is chiefly augmented by the large market, held in the town on Sunday. The market is of great antiquity, and its former importance is indicated by the circumstance of its having given name to the county, which is called in the Saxon Chronicle Wilton, and which appears to have obtained its name from the river Willy (Wilton), on which it still stands. It was the scene of one of Alfred's early battles with the Danes (a.d. 871), and some have supposed to be the Eftelunde of the Saxon Chronicle and other ancient authorities, where Egbert conquered (a.d. 803) the Mercian King Beornwulf, and established the perpetual supremacy of the West Saxon dynasty. Wilton was an occasional residence of the West Saxon kings; and an abbey was founded here for nuns, which was either originally or soon became a Benedictine monastery. It was plundered and burnt by the Danish King Svend in the reign of Ethelred II. (a.d. 1003), but appears to have so far recovered as to be a place of importance at the time of the Conquest. It received a charter from Henry I. In the civil war of Stephen, the king was said to fortify the monastery in order to check the advance of Maud the empress had made to Old Sarum, when he was attacked by the army of the queen, led by Robert, earl of Gloucester, the empress's chief supporter. The yearly revenue of the abbey, dissolved by Edward I., was 6522. 11s. 4d., gross, or 601l. 12s. 4d. clear. Wilton was for a time (a.d. 909-1043), or later, the seat of a bishopric formed by the dismemberment of the extensive See of Bath and Wells. The church of St. Peter and St. Paul, now a large manor house, was before the removal of the see to Sarum. [SERTM.]

In statistics of the borough and parish of Wilton in 1831 were as follows:—

The borough has been enlarged for parliamentary purposes, by the addition of the parishes of Fingeston, Under-

ford-under-the-Castle, Grimsell, Northumberland, South Newton, Wishford, Barford, Burcombe, Netherham-"
The town hall at Hatherleigh is a notable building, and there are places of worship for Methodists and Congregationalists. The church is a large stone church with a stone and slate shingles, shingled and pointed, with a tower at the intersection of the nave and chancel, it contains a number of monuments.

There are two Sunday-schools, with Slaggy, and Sunday schools included in the above figures. One Sunday-school has 150 children, and the other 100 children, and a total of 250 children are taught.

The town hall at Hatherleigh is a notable building, and there are places of worship for Methodists and Congregationalists. or one in six of the population under instruction on Sundays.

Ludgershall is in the hundred of Amesbury, 74 miles from the General Post-Office, London; by the Great Western Railway, to Bristoe, and from thence by Andover. The town is called Littlegarsele in Domedey. It had a castle erected soon after the Norman Conquest, of which there are some remains. It sent members, though not uninterruptedly, from the time of Edward I, to the passing of the Reform Act, when it was disfranchised. The borough is not noticed in the Municipal Corporations Reform Act. The statistics of the borough and parish, in 1831, were as follows:—

<table>
<thead>
<tr>
<th>Area in acres</th>
<th>Inhabited. Uninhabited. Building. Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>1600</td>
<td>116 4</td>

<td>536</td>
</tr>
</tbody>
</table>

The town is in a pleasant situation: the streets are neither paved nor lighted. The church is of irregular form, with nave, chancel, and two transepts of very unequal dimensions. The nave and chancel are separated by a pointed arch, the archway being occupied by a wooden screen, and there is a low squint or western tower of irregular shape, built of flint and brick. The market has long been given up, but a mutilated stone cross distinguishes what was formerly the market-place. There is a considerable vicarage. The living is a vicarage of the clear yearly value of 374L, in the rural deanery of Amesbury, in the archdeaconry and diocese of Salisbury. There were in the parish, in 1833, three day-schools, supported by subscription, with 46 scholars, viz. 28 boys and 18 girls, giving instruction to one in every four of the population under daily instruction. There were no Sunday-schools.

Wootton-Basset is in Kingsbridge hundred, 87 miles from the General Post-Office, London, by the Great Western Railway, which passes near the town. It is called in Domedey, Woteitone; and was held by Milo Crispin, but afterwards passed to the Bassetts of Wycombe, from whom it obtained its distinguishing epithet. The town sent two members to parliament from the time of Henry VI, to the passing of the Reform Act, when it was disfranchised. It is on an elevated site, and consists chiefly of one street along the road from Cricklade to Calne, lined with houses, built chiefly of brick and thatched. The statistics of the borough and parish, in 1831, were as follows:

<table>
<thead>
<tr>
<th>Area in acres</th>
<th>Inhabited. Uninhabited. Building. Total</th>

The church is an ancient structure in the centre of the town. The market is on Tuesday, and there are six yearly fairs. The corporation is not noticed in the Municipal Corporations Reform Act. The living of Wootton Basset is a vicarage of the clear yearly value of 461L, with a glebe-house, in the rural deanery of Avebury, in the archdeaconry of Wilts, in the diocese of Salisbury. There were in the parish, in 1833, nine day-schools, with 197 scholars, namely, 38 boys and 59 girls, and 121 children of sex not stated, giving from one in nine to one in ten of the population daily instruction. In the Sunday-schools, with 214 scholars, namely, 100 boys and 54 girls, and 60 children of sex not stated in the return, giving about one in nine of the population under instruction on Sunday.

Highworth is in the hundred of Highworth, Cricklade, and Staple, 79 miles from the General Post-Office, London, by the Great Western Railway to Shirehampton, which is distant from Highworth four miles. The parish has an area of 961 acres; it is divided into seven chapels or tythes, and contained, in 1831, a population of 3127. Highworth tything had at that time 130 houses, namely, 123 inhabited, 6 uninhabited, and 1 building, with a population of 124 families, or 632 persons, about one-sixth agricultural. The traffic is on a hill by the road between Lechlade and Swindon: it is neither paved nor lighted. The houses are mostly built of stone, of which there are quarries in the neighbourhood. The church is in the middle of the town; it is an ancient building, having a chapel on the south side, hung round with pieces of ancient armour; it is a Gothic structure. On Wednesday, and there are two yearly fairs, namely, a cattle fair and a statutory fair for hiring servants. The town was formerly incorporated, but lost its privilege of sending members to parliament through disease, and the corporation has ceased to exist. The town is a vicarage with chapels of Broad Bumpstead, South Marston, and Sevenhampton, all in the parish, at the joint clear yearly value of 463L, with a glebe-house, in the rural deanery of Cricklade, in the archdeaconry of Bristol, in the diocese of Gloucester and Bristol. There were in the whole parish, in 1833, 500 children, and four other day-schools, with 159 scholars, namely, 117 boys and 42 girls, giving about one in five of the population under daily instruction; and three Sunday-schools, with 417 scholars, namely, 225 boys and 192 girls, giving about one in the week. One of the Sunday-schools was partly supported by endowment and subscription.

East or Market Lavington is in the hundred of Swavesey, 113 miles from the General Post-Office, London, by the Great Western Railway to Chippenham, and from thence by Devizes. The parish, including the tything of Easterton, has an area of 594 acres, and had, in 1831, 330 houses, namely, 319 inhabited, 7 uninhabited, and 4 empty. There, with a population of 1523 persons, namely, about two-thirds agricultural. The town is at the valley between the green sand and chalk hills on the north-west side of Salisbury Plain; the two principal streets cross each other at right angles; and the hamlet of Easterton, nearly 1 mile from the town on the north, is an ancient town in the town, and is of Gothic architecture of the later perpendicular period. The market, if continued, is on Wednesday, and there is one yearly fair. The living is a vicarage, of the clear yearly value of 300L, with a glebe-house, in the rural deanery of Lavington, in the archdeaconry of Wilts, in the diocese of Salisbury. There were in the whole parish, in 1833, five day-schools with 87 children, namely, 26 boys and 46 girls, and 15 children of sex not stated, giving about one in seventeen of the population under instruction on Sunday. In the Sunday-schools, with 262 scholars, namely 121 boys and 141 girls, giving one in six of the population under instruction on Sunday. Bishop Tanner, author of "Notitia Monastica," was a native of Market Lavington.

Melksham is in the hundred of Melksham, about 91 miles from the General Post-Office, London, by the Great Western Railway to Chippenham, and from thence through Laycock. At the time of the Domesday survey the manor belonged to the crown, and is stated to have been a place of some consequence; but it afterwards declined, and continued in obscurity until it was revived by the introduction of the cloth manufacture; but that branch of industry has of late years somewhat declined. Some of the ancient mineral waters were discovered in the town; and hot and cold baths have been established, and houses built for visitors to the Spa. The parish has an area of 8920 acres, without including the chapel of Seend, which is a dependency of it: it had, in 1831, 366 houses; namely, 942 inhabited, 48 uninhabited, and 5 building, with a population of 973 families or 4722 persons, about two-sevenths agricultural. The town consists principally of one long winding irregular street, chiefly along the road from Bath to Devizes, but parallel to the road from Blandford. One part of the town is divided by the river Avon, over which is a bullock-stayed stone bridge of four arches, from a suburb called the city, a design which has led to the conjecture that it was built by a Roman station. The history or tradition to think it was. The houses, which are of stone, are of neat appearance; and the main street is paved and lighted with gas. The church, which backs from the street, on the west side of the town, is a one church, with some Norman remains, which rise early from the intersection of the nave and transept, and two chancel chapels on the south side. There are place of worship for Baptists, Independents, Wesleyans, and Quakers. The principal manufacture is the cloth and hosiery, with some corn. The population, in 1831, about 170 men. The market is held once a fortnight for cattle, pigs, &c. on Monday; and there is one yearly fair.
There are petty sessions once a fortnight, and a court for the recovery of small debts is held once in three weeks. The living is a vicarage, united with the chapelry of Seend, Earl-Stoke, and Shaw, of the joint clear yearly value of £165, with a glebe-house, in the rural deanery of Potter, in the archdeaconry of Wilts, in the diocese of Salisbury.

There were in the parish, without including the chapelry of Seend, in 1833, five day-schools of all kinds, with 320 scholars; namely, 180 boys, 90 girls, and 59 children of school age, and twenty-two street schools, with 675 scholars, of sex not stated in the return; giving one in fifteen of the population under instruction daily, and one in seven under instruction in the week. One of the day-schools was an infant-school, with 50 children; and two others were for infants and children, with 200 children, of both sexes; all three partly supported by subscription, and the Lancasterian schools having also a small endowment.

Mere is in the hundred of Mere, 104 miles from the General Post-Office, London, by the South Western Railway to Basing-stoke, and from hence to Andover, Amesbury, and Hindon; or 22 miles west of Salisbury through Basing-stoke, with its market-town, and on the road from London and Salisbury to Winchester and Exeter. The church, which is on the south side of the town, is a handsome Gothic building, chiefly of perpendicular character, having a western tower, with battlements and a spire. The town contains 2,000 persons; and has a market-day on Tuesday, and a fair on the third Wednesday after Trinity Sunday. There are two large yearly fairs. The living is a vicarage, of the clear yearly value of £280, with a glebe-house, in the rural deanery of Wiltshire, in the archdeaconry of Wilts, in the diocese of Salisbury. The parish contained, in 1833, nine estates of 300 acres, with 12 manors; 201 households, with 1,178 persons, of whom 450 were males, and 728 females; 181 inhabitants, and 399 acres of waste and heath; one school, with 40 boys and 10 girls; supported by an endowment.

Trowbridge is in the hundred of Melksham, 120 miles from the General Post-Office, London, by the Great Western Railway to Bath, or the Bath and North Western via Swindon, with its castle or fortress, which was garrisoned by the supporters of the Empress Maud, and taken by the king's forces. John of Gaunt either repaired this castle or built a new one; but it was burned down in 1360. He told the townsmen that there was only a part of two. The castle stood on the south side of the town, near the river Wilt. There are no remains now, and its site is built over. The parish contained, in 1801, 2,580 houses, and 1,195 inhabited, 1,915 uninhabited, and 3 building; with a population of 2,073 families, or 10,863 persons, a very small part agricultural. The town is on a rocky hill on the north-east bank of the Wilt, a tributary of the Avon; it was probably in the time of the Romans, and it has for a spacious edifice, with a nave, chancel, two aisles with chapels attached to their eastern extremities, a north and a south porch, and a large western tower and spire. The ceiling of the nave is flat, and is ornamented with rich inlay-work. There are two district churches or chapels-of-ease in the parish, namely, Trinity church or chapel in the town, and Staverton chapel, in the hamlet of Staverton, about two miles from the town. There are four public schools, two for boys and two for girls, and a day-school for young persons; a general and particular Baptist chapel, and a Wesleyan chapel. And there are two district schools for infants, one in the town, and one at Staverton. Trowbridge is the largest town in the county and one of the largest in the west of England. The clothing trade is of considerable antiquity here. Eardis says of Trowbridge, 'Here is a very rockie hill, with a good build of stone, and florishing by drapery.' He mentions some of the great clothiers of the place, and records their benefactions to the town. The market is on Saturday; some of our authorities give the place three markets weekly, on Monday, Saturday, and Saturday and Sunday, which last day seems to be the fair. Petty sessions are held monthly, and there is a court of requests for the recovery of small debts, which holds its sittings every three weeks. The living is a rectory united with Staverton, and worth £500 a year, and is held by the Rev. Dr. Wharton, of the see of St. Asaph. There are four churches in the town, and six or seven in the surrounding district. There are numerous chapels and places of worship. The market is on Monday for corn and other commodities, and for cattle every alternate Monday; there are five yearly fairs. There is a mill, with an overshot wheel of unusually large diameter, which is supposed to be the remains of a old watermill, of the same formation as the Portland stone, which employs a considerable number of men; the stone is used for troughs, t offices, miles-stones, &c. The living is a vicarage, of the clear yearly value of £200, with a glebe-house, in the rural deanery of Bristol, in the archdeaconry of Bristol, in the diocese of Gloucester and Bristol. There were in the parish, in 1833, seven day-schools of all kinds, with 185 scholars; namely, 92 boys and 93 girls; and three Sunday-schools, with 194 scholars; namely, 84 boys and 110 girls; giving between one in nine and one in ten of the population under instruction daily, and one in seven under instruction on Sundays. One of the day-schools, with 40 boys and 10 girls, was supported by an endowment.
and comprised, in 1831, 1308 houses, namely, 1236 inhabited, 37 uninhabited, and 13 building; with a population of 6151 souls. About three miles west of the Wiltshire, is the town of Chippenham. The town is in a very healthy situation, close to the western border of Salisbury Plain, in the valley of the Wilt, the north of the river itself: it consists of several streets, the principal one of which, trending along the road from Salisbury to Frome. The principal street is well paved; and the general appearance of the town is neat and respectable. The parish church stands on the north side of the town, on the Bath Road, and is dedicated to St. Denis: it is a handsome and large edifice, built of stone, and is considered the most ancient church in the town, and is now used as a chapel of ease.

Some scholars, of the early 19th century, have questioned the antiquity of Selkley, or Selkley-with-Salterne, founded as a town in the time of Edward I., and now used as a chapel of ease. There are places of worship for Baptists, Independents, Wesleyan Methodists, and Presbyterian Unitarians. There is a handsome town-hall erected on the market-place, with a handsomely set of rooms for assemblies, public meetings, &c. The market is held on Saturday, and there are three yearly fairs. The market is a considerable corn-market, though it has been injured by the rivalry of Devizes, which has a considerable trade in cattle. The fact that Salisbury is a market town is called, by way of eminence, 'the great fair,' and is a considerable cattle, sheep, and cheese fair. The woollen manufacture which was formerly carried on is now almost extinct, and the silk manufacture, which was introduced some time since, is now of little importance.

It 1931, thirty-seven-day schools of every kind, with 911 scholars, namely, 494 boys and 417 girls; nine Sunday-schools, the national school, which was a grammar school also, with 1061 scholars, namely, 555 boys and 506 girls; giving above one in seven of the population under daily instruction, and above one in six under instruction on Sundays. Of the day-schools, twenty-three schools, with 350 scholars, were dame-schools or other schools for small children; one was a national school with 140 boys and 60 girls, and 40 girls additional on Sundays; one was a Lancing school with 80 girls; and one was an endowed grammar-school with 48 boys. These schools are entitled to notice. Aldbourne (colloquially pronounced Aubourn) is in the hundred of Selkley, about six miles north-east of Marlborough. It is beautifully situated in a valley, and was anciently a place of importance. In modern times, it has twice suffered severely from fire. In 1760 a conflagration destroyed more than seventy houses; and in 1817 twenty were consumed. The earl of Essex was burned here by the royalists in the great civil war A.D. 1643. Aldbourne Chace, an extensive waste, with a large rabbit-warren on the north and north-west of the village, was formerly well wooded and stocked with deer. The area of the parish is 6000 acres; the population, in 1831, was 1418, from one-third to one-half agricultural. Aldbourne had formerly a market and fair, but they have been discontinued: a small manufacture of hustings was carried on for a few years, but if it now exists it is much reduced. Steeple Ashton is in Whorwell-land, about three miles east of Trowbridge, a former market town, and in which the land's time was the seat of a considerable clothing manufacture. It has a lofty and elegant church, with nave, chancel, side aisles, north and south porches, two small chapels, and a large western tower. Both church and tower were built by Battlements and pinnacles. The tower has a fine western window and was antiently surmounted by a stone spire, or, as Leland calls it, a 'spirel of Steeple Ashton;' which gave to the village its distinguishing epithet of Steeple Ashton. The spire was destroyed in two thunderstorms of July and October 1611, together with the lead from pavement, differing from the usual style and materials of Roman pavement, was dug up at Steeple Ashton. The area of the parish is 7460 acres: it is divided into five chaplaries or tythings. The population of the tything of Steeple Ashton, in 1631, was 949; of the whole parish, 1851, Box is in the hundred of Chippenham, about five miles east of Bath, in a beautiful valley watered by a small stream called the Leach. The number of inhabitants is about 7000. There are considerable quarries near Box, of the freestone usually called Bath stone, and there are two mineral springs. The area of the parish is 4140 acres; the population, in 1851, was 1560. Some men were employed in stone quarries or on the roads. The Great Western railway passes near Box, and the longest tunnel on the line is near this place. North Bradley is in the hundred of Whorwell-land, two miles south of Trowbridge. The parish consists of an ancient park of which there is an ancient house called North Bradley Court. The old house of North Bradley Court is a large and handsome building, formerly held by the Earls of North-Bradley, and now a farm; the population of North Bradley, in 1831, was 152; that of the rest of the parish, including the village of North Bradley, 1025; together, 2147, about one-fourth agricultural. The manufacture of broad cloth and knee-breeches is carried on in this parish. The parish is in the hundred of Bath, the Baptist church was built in 1831 to 91 men. Bratton is just at the foot of the north-west escarpment of the southern or Salisbury Plain chalk district in Westbury hundred. It is a hamlet of Westbury, from which it is distant 40 or three miles north-east. Bratton camp is an ancient entrenchment of irregular form, nearly a mile in circuit, and enclosing an area of twenty-three acres, on the edge of the chalk downs between the village and the town of Westbury. On the south-eastern escarpment, near the camp, is a tumulus supposed to be a memorial of Alfred's victory at Eddington, but which is positively asserted by others to be of modern date. Bromham or Breham is in the hundred of Poterne and Cannings, four miles north-west from Devizes. The town of Bromham consists of three villages: the church of St. James in Bishop's-Cannings, a large village, included in the new boundary of the borough. The population of the parish, in 1831, was 1330. The village of Bishop's Cannings is in the valley beneath the southern escarpment of the northern chalk district, to the left of the road from Marlborough and Devizes to Coggeshall; is a handsome church, with nave and side aisles, transept, south porch, a chantry altar at the east side of the transept, another chantry chapel, and a lady chapel, now used as the chancel. Some parts of the old church are Early English, and the battlements and some windows in the nave are of a later period: the tower and spire rise from the intersection of the nave and transept, and are of Early English character. Corsham, formerly a market-town, is in the hundred of Chippenham, about three miles west-south-west of Chippenham. The parish has an area of 6710 acres; the population, in 1831, was 2994, nearly one-half agricultural. The village is in a healthy situation and consists of a long street, with the houses built of stone with a market-house in the centre, built A.D. 1784, by Mr. Methuen, with the vain expectation of reviving the market. The church is a large antient building, lying back from the church, close to Corsham Park, the seat of Lord Methuen, the present owner of the manor of Corsham. Corsham House is building of the age of Elizabeth of very incongruous architecture: it contains a very fine collection of paintings, formed by Sir Paul Methuen, as a gentleman diplomatist, early in the last century. Sir Richard Blackmore, the poet, was a native of Corsham. Long-

Deverfaill or Deverill is in the southern division of

Damerham

hundred. It is called Longbridge Deverhill to
distinguish it from four other villages to which the name of
Deverhill is common, all lying within about three miles
south of Longbridge Deverhill, and one of them, Hill Deverhill. immediately adjacent to it. Longbridge Deverill
parish has an area of 4230 acres ; the population, in 1831,
was 1307, more than a third agricultural : the clothing
manufacture employed above fifty men.
Dilton is a
suburb of Westbury, of which parish it is a chapelry. The
chapel is about a mile from Westbury : the population of
the chapelry, in 1831, was 2172, of whom 200 men were
employed in manufacture chiefly or wholly of woollen
cloth and kerseymere. Hilperton is little more than a
mile north-east of Trowbridge ; it shares in the cloth and
kerseymere manufacture of that town, which gave employment to 85 men in Hilperton parish in 1831. The area of
the parish is 980 acres ; the population, in 1831, was 1067.
Kingswood is in a portion of Chippenham hundred insulated in Gloucestershire, about a mile south by west of
Wootton-under-Edge. There was formerly a Cistertian
abbey here, founded a.d. 1139: it was almost forsaken
toon afterwards by the removal of the monks to Haselden,
and afterwards to Tetbury, Kingswood becoming a cell
with only a monk or two to say mass ; but about a.d. 1170
the abbot 'and monks returned to a place called Mere wood,
in Kingswood parish, where the village now is, near the
site of their former seat.
The revenues of the abbey at
the dissolution were estimated at 254/. lit. 2d. gross, or
244/. 11#. 2d. clear, according to Speed andDugdale. The
statement of a MS. Valor, quoted by Tanner, differs a little
from this account. Part of the conventual buildings, consisting of the gate-house of the abbey and a range of buildings on each side, lately occupied as separate dwellings,
but now in ruins, are still standing. The area of Kingswood parish is 2320 acres; the population, in 1831, was
1447. of whom 123 men were employed in the woollen
eloth manufacture.
East Knoyle. in Downton hundred,
about two miles south-west of Hindon (area of parish
5320 acres ; population, in 1831, 1028, chiefly agricultural)
wis the birthplace of Sir Christopher Wren, whose father
was rector of the parish. Ramsbury is in Ramsbury hundred,
miles north-west from Hungerford. It was made
tbe seat of the bishopric erected in the ninth or tenth
century by the dismemberment of Wiltshire from the
diocese of Sherborne ; the see was removed after an interval to Wilton, but at what period is doubtful ; and was
afterwards reunited to Sherborne, the cathedral being
fixed at Old Strum, from which it was removed to
Salisbury.
The area of the whole parish, which is divided
into three tything*, is 9960 acres ; the population, in 1831,
was 2290, of which the town tything contained 1538. The
church is spacious, and consists of a nave and two aisles,
» chancel, and a massive western tower. Ramsbury manor
»od house belong to Sir Francis Burdett. Sheraton Magna,
or Great Sherston, is in Chippenham hundred, about six
miles west of Malmesbury.
The area of the parish is 4140
teres ; the population, in 1831, was 1361, principally agricultural.
Sherston is thought by some to be the Sceorttane of the Saxon Chronicle, the scene of an indecisive
battle (aj>. 1016; between Edmund II. (Ironside) and
Canute, who engaged during the battle in personal conflict.
The village is partly within the site of an antient
encampment, part of which is obliterated. There is a
local tradition of a conflict between the Saxons and Danes,
ia which the Saxons were commanded by a warrior called
Rattlebone.' of whom a gigantic figure is seen on the sign
of an inn.
Rattlebone is thought to be a popular traditional
name of Edmund II. The church at Sherston is a very
large cross church, comprehending a nave, two aisles,
transept, and large south porch.
Ft is of various dates,
partly Norman, partly later.
South wick (population, in
1831, 1452) is a tything of North Bradley in Whorwekdown hundred, two miles south-south-west of Trowbridge.
The cloth manufacture employed, in 1831, 113 men.
Wiasley and Limpley-stoke are chapelries in the parish
ind hundred of Bradford; Winsley about a mile, and
Umpley-ttoke about two mile* west of that town. The
population of the two chapelries, in 1831, was 2847 ; the
doth manufacture gave employment to 245 men.
Division* for Ecclesiastical and Legal Purposes. The
county was formerly included in the diocese of Salisbury,
tnd was divided into the two archdeaconries of Sahsbwy

L

I

and Wilts. The archdeaconry of Salisbury comprehended
the five rural deaneries of— (1) Amesbury, (2> Chalke or
Chalk. (3) Pottern, (4) Wilton, (5) Wylie or Wylye ; beside the deanery of Salisbury, which consists of the three
parishes of that city
the archdeaconry of Wilts comprehended the four rural deaneries of— (1 ) Avebury, (2) Cncklade, (3) Malmesbury, (4) Marlborough. By the late alterations, in pursuance of the recommendation of the Church
Commissioners, the rural deaneries of Cricklade and
Malmesbury have been transferred to the archdeaconry of
Bristol, in the diocese of Bristol and Gloucester ; and the
rural deanery of Pottern has been transferred from the
archdeaconry of Salisbury to that of Wilts. The total
number of ecclesiastical charges in the county is, as near as
we can ascertain, 336; but as some of these are permanently united, the number of benefices is only 273. Hie
ecclesiastical charges and benefices are arranged as follows :
I. Diocese of Salisbury.

Wiltshire is in the western circuit : the spring assizes are
held at Salisbury, tbe summer assizes at Devizes. The
judges proceed to those places from Winchester ; and go
from them to Dorchester. The Epiphany and Easter quarter sessions for the county are held at Salisbury ; the midsummer sessions at Warminster, and the Michaelmas sessions at Devizes.

At the commencement of the year 1836

there were four
one, a county gaol, at
Fisherton Anger, a suburb of Salisbury; two at Devizes,
the old bridewell and the new house of correction ; and
one. a bridewell, at Marlborough. But since that time the
old bridewell at Devizes has been given up. The county
gaol at Fisherton Anger contains 112 sleeping cells and 5
dark cells ; with 10 day-yards, all gravelled and partially
paved. Each prisoner eats and sleeps in a separate cell,
and only four or five are allowed to be in the yard together.
The prison is not made so useful as it might be ; as many
as 50 cells have been empty at one time, and that
prisons belonging to the county

:

while the prisons at Devizes and Marlborough were full to
overflowing. The majority of the inmates are prisoners
for trial.
The prison is neat and clean and well arranged
it is so built that every sound is heard, even a whisper lias
been said to have been heard at night. The labour is very
light.
The house of correction at Devizes contains 235
sleeping cells, 38 of which are for women ; an addition of 40
There are ten wards or di vicells has been lately made.

without restraint; but the convicted are kept, as far as possible, in separate cells. There is no regular labour for the men: the women sometimes wash and mend the clothes. The arrangements of the prison are in several respects defective; but it is kept neat and clean, and the keeper appears to perform his office, amid many difficulties, in a methodical and careful manner. (Inspectors of Prisons' Second, Fourth, and Seventh Reports.)

Before the Reform Act thirty-four members of parliament were returned from Wilts; namely, two for the county, two for the city of Salisbury, and two each for the boroughs of Great Bedwin, Calne, Chippenham, Cricklade, Downton, Heytesbury, Hindon, Loderslack, Malmesbury, Marlborough, Old Sarum, Westbury, Wilton, and Wotton-Basset. By the Reform Act, Great Bedwin, Downton, Heytesbury, Hindon, Loderslack, Old Sarum, and Wotton-Basset were altogether disfranchised; and Calne, Malmesbury, Westbury, and Wilton reduced to one member each. The county was formed into two divisions, each returning two members; so that the number of members is now eighteen, returned as follows:

The northern division of the county comprehends the hundreds of Bradford, Calne, Chippenham, Damerham (North), Highworth, Cricklade, and Staple, Kingsbridge, Melksham, Malmesbury, Melksham, Potters and Cannings, Ramsbury, and South Cerney. By the court of election is held at Devizes; and the polling places are Devizes, Melksham, Malmesbury, and Swindon.

The southern division comprehends the hundreds of Alderbury, Amesbury, Branch and Dole, Cawden and Cadworth, Chalke, Damerham (South), Downton, Duncombe, Elstub and Everly, Frutfield, Heytesbury, Kinwardstone, Mere, Underditch, Warminster, and Westbury. The court of election is held at Salisbury; and the polling places are Salisbury, Devizes, Everly, Hindon, Street, and Warminster.

The detached portions of the county were by the Boundary Act added to the counties in which they are respectively insulated.

In consequence of the bribery proved to exist in the borough of Cricklade, the elective franchise of that borough was extended (a.d. 1792) to the freeholders of the hundreds of Highworth, Cricklade, and Staple, Kingsbridge, and Melksham. With the exception of Cricklade, all the boroughs in the county were enlarged by the Boundary Act, some of them very considerably, by the addition of a number of rural parishes. This was especially the case with Malmesbury and Wilton. By the Municipal Reform Act, the extended parliamentary boundaries of Devizes and Salisbury were adopted for municipal purposes.

History and Antiquities.—Wilts is probably the richest, of all the English counties, in memorials of the earliest historic period, and indeed of the ant-historic period of our country. This pre-eminence it owes to the wide extent of the chalk district, in which the earth which the chalk containing, was untouched by the plough, on which the earth or rude stone memorials of the remotest ages have remained uninjured, except by the mouldering touch of time, or by rare and occasional interventions of the caprice and violence of man; exempt in a great degree from the more systematic and complete destruction which the extension of building or cultivation has caused.

It is difficult to determine exactly to which of the ancient Britons the various parts of the county belonged.

A large portion, there can be no doubt, belonged to that nation or those nations who are mentioned by Ptolemy under the generic name of Belgae (Belg.i). Ptolemy assigns to them the cities of Iscalesia (Twyford) and Aquis Calidiae (Wyse Thera), now Hillesdon and Bath in Somersetsire, on the one hand, and Venta 'Glaston,' now Winchester in Hampshire, on the other. We may therefore assume that the inhabitants of the part of the country which lies between these places. Possibly some parts of the south-western border, about Mere and Hindon, may have belonged to the Durtrigores (Durtrigores, T polyem), who occupied Dorsetshire; and some parts in the north-east side of the county probably belonged to the Atrebates (A terbates, Ptolemy), whose chief town was Calleva (Camelot, Ptolemy), now Silchester, on the border of Berkshire and Hampshire. It is not unlikely that the upper Thames, which may be assigned to the Dobuni (Duoboni, Ptolemy), whose chief town was Calleva (Aquitania, Ptolemy), now Silchester, and Corinium (Corinium, Ptolemy), now Cirencester.

By Richard of Cirencester the towns of Iscalesia and Aquis Calidiae, or, as he terms them, Thermes, or Aquis Solia (probably an error for Sulia), were assigned to the Vedones, or Vedones, to the Hedoni; in which case it is not unlikely that the western part of the county of Wilts may have belonged to that people. But it is to be observed that Richard appears to be at issue in this matter with Ptolemy, who, as we have seen, assigns them to the Belgae. The Celtic origin of the Hedoni (supposing them to be of the same race as the Gallic nation so called) makes it difficult to suppose that they are included by Ptolemy under the name Belgae. Yet a passage in Richard indicates that the name of Belga was a term applied to a race of people: "For all the Belgae were Allobroges, and derived their origin from the Celtae and Belgae." In the revised Richard's book published in 1809, Allobroges is interpreted to mean "foreigners," which is no more than an error of the original. It is however possible that the name of Belgae may have been given by Ptolemy to a great confederation of which the predominant tribes were of Belgae race; and that the Hedoni, so powerful in Gaul in British History, a subordinate member of that same confederation. Richard assigns to the Segontii a position near the river Cunetium (or Kennet) and a city called Vinoundum, which he elsewhere enumerates among the trubary and less important cities (civitates superstitionis); but from various other monuments the name and map appear to place the Segonti in part in Wilts.

It is likely that the county was included in the scene of Vespasian operations in the reign of Claudius, when he subdued two very powerful nations (of whom Richard of Cirencester states that his son, Natan-leod, was one), conquered the Isle of Wight, and sided in reducing the southern part of Britain into the form of a province. (Suetonius, Vespasianus, c. 4.) In the Roman division of the province Wilts was included in the province of Britannia Prima.

After the departure of the Romans, Wilts was the scene of contest between the Britons and the Saxons. The scene of the asserted massacre of the British nobles by Hengist and his brother Aelle is placed in the county of Wilts (see History and Antiquities), and its locality are doubtful. The great victory which Cerdic, founder of the kingdom of Wessex, obtained (A.D. 586) over the British king Natan-leod or Nazaleod, brought the conquerors to the south-eastern border. Cerdic, the Cerid's ford of the Saxons Chronicle, was on the Avon, above Fordingbridge, in Hampshire, but close to the Wiltshire border, was the limit of the territory 'Natan-leaghe' (a name which seems to be preserved by Nettle Abbey, in Hampshire), to which Natan-leod gave Cerdic. It does not appear to have been an island or subdumb Wilts then. The Saxons Chronicle is silent about him for many years; and when he is next noticed (A.D. 519) it is on occasion of a victory gained by him and his son Cynegils at Cerneford near Cerne Abbas above mentioned. Then it may be doubted if much of Wilts was subdued for many years afterwards (A.D. 583) we find Cynric, son of Cerdic, in successful conflict with the Britons at Sandrig or Old Sarum. The West Saxons, of whose kingdom the Saxons Chronicle speaks, made an unsuccessful attempt to extend their power northward, to and even beyond the Thanes, rather than westward. However, before or in A.D. 577, they must have overrun Wilts, as we find in that year, under their king Cynric, that the Britons in the north of Sommergehe and in Gloucestershire, to which they must have crossed Wilts. Whether they suffered any repulse, or the Britons retaliated their invasion, is not clear; but in A.D. 591, according to the Saxon Chronicle, there was a great

A
bourn—St. George to the station at Folly Farm, near Marlborough, coinciding with modern roads or lanes. From Marlborough, may be traced, running south-westward by a built avenue across Savernake Forest and the grounds of Savernake House and Tottenham Park, by Crofton, Wilton, Marton, and through Conhol Park into Hampshire, at Hampshire Gate, and so to Venta Belgarum or Winchester. Just before quitting Wilshire it makes a sudden bend, very unusual in Roman roads, to avoid a declivity.

The Roman road, known in later times as the Port Way, from Calleva (Silchester) to Sorbiodunum (Old Sarum), entered at Hampton-Common, near Newbury, and runs by Porton and Winterburn-Gunner.

Another road, coming apparently from Spinae (Spina near Newbury), is traceable just on the border of the county near Tidcombe, 4 miles north-east of Luddington, running in the direction of Sorbiodunum.

There are some traces of a Roman road from Folly Farm by Marlborough, running due south in the direction of Sorbiodunum or Old Sarum. Possibly the road from Spinae has not noticed unite by a

Another road is supposed to have run in a north-west direction from Sorbiodunum toward Aque Sulis, now Bath: but this is not certain.

A road from Sorbiodunum leading westward may be traced from Newbury Plain, through Greaveley Wood, by Dinton-Beeches, through Stockton Wood and the Great Ridge Wood, towards Monkton Deverhill, and Kingston Deverhill, and thence by Maiden Bradley into Somerset. It is apparently part of the road which runs through Somersetshire along the Mendip Hills towards the Bristol Channel.

Of the station Cunetio traces are found both at Mildenhall on the north side of the Kennet, and Folly Farm on the south side, and Sir R. C. Hoare distinguishes the two positions by the names of Upper Cunetio (Folly Farm) and Lower Cunetio (Mildenhall). The hill on which Folly Farm stands is covered with a variety of banks and earthworks, probably belonging to the period before the Roman domination, and it is probable that some of the earthworks are part of the Roman settlement. A portion of the rampart, which was quadrangular with rounded angles, may be seen, and in the cemetery remains, coarse tessellated pavements, medallions, and other relics have been dug up. The most remarkable of these relics was a small-boned figure of a female dressing her hair, and a bronze spoon. At Mildenhall are some traces of the rampart. It is not improbable that the town of Cunetio occupied both banks of the river, and that the two forts were for its defence, one on the north, the other on the south.

At Wanborough-Nyth and Covenham farms, where the road to Cunetio branches off from that between Durocormium (Cirencester) and Spinae (Spina), are traces of a Roman settlement; abundance of fine red glazed and thin pink pottery, and some of coarse manufacture, has been found, and inequalities in the surface of the ground, from which many large stones have been dug up, are indications of ancient buildings. Sir R. C. Hoare, without any authority, that we are aware of, that the modern name Nyth, has named this station Nidum.

The Roman settlement at Easton-Grey on the Fosse appears, from the traces of buildings, to have been of some extent, Sir R. C. Hoare identifies it, on slender grounds, with the station of Hastingley, near Ransome, and the site of any vallum, but numerous medals and a coarsely sculptured bas-relief have been found.

At Stockton Wood Corner, 104 miles from Sorbiodunum (Old Sarum), on the road which leads into Somersetshire by Aylesbury, 1½ miles north-west, is the remains of a Roman settlement; pottery and medals having been dug up. At Bishopstrow, between Warminster and Heytesbury, on the line of the supposed road from Sorbiodunum (Old Sarum) to Aque Sulis (Bath), the remains of a Roman settlement by a bank and ditch, an earthen rectangular quadrangular area of 50 acres, still called the Bury: large fragments of Roman pottery have been dug up in every part of the enclosure. At Plimead, close to Bury, are the remains of a Roman road, near the site of the station Verulanium; and at Littlecote, near Ransome, tessellated pavements have been discovered, but the principal of them were destroyed soon after they were found. At Rudge a brass cup and some medals were found in a well; the cup was inscribed with the names of several of the stations on the Roman wall in Northum-

Of the antiquities, not Roman, the most striking are those of Stonehenge and Avebury or Abury. [Stoneshenge; Avebury.] There are some traces of a British or track-way, known as the Ridge-way, running across Salisbury Plain, near Newbury, down to the town of Newbury, and near Marlborough, passing through the county of Berkshire; throughout which county it may still be traced.

Wansdyke, or Wansditch, is a vast earthen rampart, with a ditch on the north side, which extends, though not uniformly, through the country for the first undistinguishable part. Of Wansdyke, westward, is at Maes Knoll Camp, about five miles south-south-east of Bristol. It may have been traced at intervals in Somersetshire, by Stanford Camp, to the neighbourhood of Bath, where a small part of it may be still discernible, near the Warmminster and Shrubb ford, a part extending across Claverton Down to Bathampton Camp. From thence its direction is doubtful; it is supposed to have coincided, for many miles, with the line of the Roman road from Aque Sulis to Cunetio. At Warminster's Hill, three or four miles north of Wiltbridge, it again appears, diverging from the course of the Roman road, and running across the chalk downs of the northern chalk district, not far from its southern extremity, which one its said to have been the cause of the ravine through which the river Wilt passes, where it suddenly bends to the south-south-east; it afterwards turns more to the east, and enters Berkshire. Its length, in Wiltshire, from its divergence from the Roman road to the Berkshire border, is about 10 miles including gaps. The origin of Wansdyke is unknown. The old popular tradition, which was evidently connected with its name, was, that it was made by the devil on a Wednesday. Aubrey supposed it to have been the ancient boundary of the kingdoms of Wessex and Mercia, which once it was considered as.

Stokesy supposed it to have been made by the Belgae, to secure their territories from the Celtae. Sir R. C. Hoare seems to have regarded it as a Welsh work, repaired or reconstructed by the Saxons.

The surrounding numerous banks and ditches are to be traced on the downs; some probably for defence, like Wansdyke, with one rampart and a ditch: others are supposed to have been roads, and consist of a broad level way between two banks. Old-ditch may be traced on the downs, north of Warminster and Heytesbury, running eastward by Chittern, or Chiltern, and Chiltern, and on to Bath. It terminates in another ditch running at right angles to it; its length is about 11 miles, including gaps and intervals. There are no remains of the ditches which may be traced for above two miles. Grimsditch, consisting of a bank and ditch, and Bokerly-ditch, also consisting of a bank and ditch, separating at its south-eastern end into two branches, are on the downs south of Salisbury, the former being part of a British fort, the latter a short distance, the boundary of the two counties. The length of Grimsditch is about six miles; of Bokerly-ditch, including both branches, about six miles, including gaps or intervals. Both have a very winding course.

The Roman enclosures are very numerous; they are fully described in Sir R. C. Hoare's 'Antiquities of Wiltshire,' which has been our chief authority for the antiquities of the county.

In the year 1164, in the second of Edward I., a national council was held at Clarendon, two miles south-east of Salisbury, where the kings had a residence and a forest: at this council the constitutions of Clarendon were passed, restricting the power of the clergy. In the reign of...
Henry III., A.D. 1267, the statutes for the suppression of tumults, known as 'the statutes of Marlidge,' were enacted in an assembly, or council, held at Marlborough. In the War of the Roses, the men of Wiltshire generally embraced the Lancastrian side; but no great event in that war occurred in the county. The civil war of Charles I., Marlborough, which was garrisoned by the parliamentarians, was taken, with the governor and officers, and 1000 prisoners, and four pieces of cannon, by the royalists under Wilmot, A.D. 1642. In 1643 a body of royalist infantry was besieged in Devizes by Sir William Waller, but the siege was raised, and Waler defeated (13th July) on Roundway Hill, by Wilmot. Other actions of less importance were fought at Malmesbury and Ludgershall; and Wardour castle and Warminster town were beset 1704 and taken. During the time of Marlborough Wiltshire was the scene of the unsuccessful attempt of the royalists under Sir Joseph Wagstaffe. [SALISBURY.]

(Ordinance Map of England; Greenough's Geological Map of England; Conybear and Phillips' Outlines of the Geography of England and Wales; Britain's Beauties of Wiltshire; Priestley's History of Canals and Navigable Rivers; Sir R. C. Hoare's Antient Wiltshire and Modern Wiltshire; Ptolemaus Geography; Antonii Fabricii Rerum Britannicarum Historia; Salvin Chronicle; Parliamentary Papers.)

STATISTICS.

Population and Occupations.—As an agricultural county, Wiltshire was the tenth in rank in 1831, standing between Suffolk and Oxfordshire. The proportion of the agricultural population was 48.5 per cent. in 1831, at which period there were 3387 occupiers of land employing labourers, 1293 occupiers not employing labourers, and the number of agricultural labourers was 24,708. The remainder of the male population, aged 20 and upwards, was distributed as follows:—3407 employed in manufactures; 13,069 in retail trades and handicrafts; 1722 capitalists, bankers, and members of the professions; 4826 non-agricultural labourers; 1679 domestic servants; other males aged 20 and upwards, 4338; and there were 7625 female servants. The following details refer to 1831, the Return of Occupations in 1841 not being yet published. The manufacture of fine brocadel and of kerseymere employs more than 1000 men at Towcester. 600 at Bradford, 200 in the parish of Westbury, 170 at Melksham, 170 at Kingswood, 170 at North Bradley with Southwick, 85 at Hilperton, 65 at Chippenham, 62 at Bromham, 52 at Longridge, 35 at Heytesbury, 35 at Calne, 35 in the parish of More, and a few in various other places, and the total number throughout the county exceeds 3000. At Wilton about 40 men are employed in making carpets, and a few at Burcombe. A small manufactory of horsehair exists at Britford.

On the supposition that the registered baptisms, marriages, and deaths, bore the same proportion to the actual population as in 1801, the population of Wilt, in the undermentioned years, would be as follows:—95,801 in 1570, 119,672 in 1600; 146,799 in 1630; 128,969 in 1670; 159,072 in 1700; 177,089 in 1750. The population actually enumerated at the following decennial periods was as under:—

<table>
<thead>
<tr>
<th>Year</th>
<th>Male</th>
<th>Female</th>
<th>Total</th>
<th>Increase per cent.</th>
</tr>

</table>

From 1801 to 1841 the population increased 73,626, or 49.7 per cent. In the three years ending June 1841, the proportion of marriages to the population was 1 in 150; births, 1 in 34; deaths, 1 in 50; the proportion for England being respectively 127, 31, and 45. In the same three years, the proportion of persons under 21 years of age, was 16.8 for women, and 8.2 for men; and in England and Wales 13.78 for women, and 4.69 for men (Fourth Report of Registrar-General). It appears from the Census Returns of 1841, that 223,395 persons, or 88.3 per cent. of the population, were born in the county; 27,570 persons, or 10.7 per cent., in other counties of England and Wales; 281 persons, or 0.1 per cent., in Scotland; 605 persons, or 0.6 per cent. in Ireland; 7 persons were born in the colonies; 169 were foreigners, and 127 British subjects born abroad. The place of birth of 1713 persons was not ascertained. According to this Census the number of persons to a square mile is 190. The population, &c. of each hundred and borough in 1841 is shown in the following table:—

P.C. No. 1734.

VOL. XXVII.—S. 5 K
In 1831 the number of inhabited houses was 46,281, occupied by 111,560 families, and there were 321 houses building, and 1897 unbuilt.

**County Expenses, Crime, &c.**—Sums expended for the relief of the poor: 1748-49-50 (annual average), 22,938£; 1775, 54,022£; 1783-84-85 (average), 62,683£. The sum expended in 1811 was 128,625£, being 13£. 10s. for each inhabitant.

1811...234,352£     24 2
1821...163,168£     14 8
1831...191,022£     16 4
1841...133,573£     10 2

In each of the following years ending 25th March, the expenditure for the relief of the poor was as under:—

<table>
<thead>
<tr>
<th>Year</th>

</table>

The number of persons relieved in these unions during the quarter ending Lady-day, 1830, was 28,136 (5069 in-door, and 24,598 out-door). In the quarters ending Lady-day, 1840, 1841, and 1842, the numbers were as follows:—

In 1840—in-door, 4009£; out-door, 25,945£; total, 30,609£; in 1841—in-door, 19,509£; out-door, 25,482£; total, 30,091£; in 1842—in-door, 5,457£; out-door, 18,270£; total, 23,727£.

The proportion in 1841 of the total number of paupers to the total population was 15 per cent, while the average for England in the same year was 9 per cent, and in no other county was the proportion so high as in Wilts. The expense for in-maintenance and out-relief was 100,142£ for the year ending Lady-day, 1842, being an increase of 4 per cent. on the preceding year. The number of adult able-bodied paupers relieved in the quarter of 1841 was 79,422£. The number of paupers charged with criminal offences in the septennial periods ending 1819, 1826, 1833, and 1842.

In 1839 the church-rates amounted to £63,894; and 141£, applicable to the same objects, were derived from other sources, the amount was £75,693 for parish churches, and £7,369 for parochial and charitable purposes.

The number of turnpike trusts in 1840, was 2; the income from tolls was £35,363£; parish poor-rates amounted to 12,902£; and the total expenditure for the same year being £26,029£.

The bond and mortgage debts amounted to £17,760£. In 1836 the debt was equal to 3½ years' income; for the whole of England the proportion of debt to income was not above 4½ years: the proportion of unpaid interest to the total debt was 13 per cent; in England 12 per cent. In ten trusts there was a surplus revenue in 1841, which, if applied to discharge the debts of each, would pay off their head-pieces debts in periods varying from twenty-two years; in two cases in twenty-one years, and in one twenty-one years.

In 1839 the church-rates amounted to £63,894; and 141£, applicable to the same objects, were derived from other sources, the amount was £75,693 for parish churches, and £7,369 for parochial and charitable purposes.

The number of turnpike trusts in 1840, was 2; the income from tolls was £35,363£; parish poor-rates amounted to 12,902£; and the total expenditure for the same year being £26,029£.

The bond and mortgage debts amounted to £17,760£. In 1836 the debt was equal to 3½ years' income; for the whole of England the proportion of debt to income was not above 4½ years: the proportion of unpaid interest to the total debt was 13 per cent; in England 12 per cent. In ten trusts there was a surplus revenue in 1841, which, if applied to discharge the debts of each, would pay off their head-pieces debts in periods varying from twenty-two years; in two cases in twenty-one years, and in one twenty-one years.

In 1839 the church-rates amounted to £63,894; and 141£, applicable to the same objects, were derived from other sources, the amount was £75,693 for parish churches, and £7,369 for parochial and charitable purposes.

The number of turnpike trusts in 1840, was 2; the income from tolls was £35,363£; parish poor-rates amounted to 12,902£; and the total expenditure for the same year being £26,029£.

In ten trusts there was a surplus revenue in 1841, which, if applied to discharge the debts of each, would pay off their head-pieces debts in periods varying from twenty-two years; in two cases in twenty-one years, and in one twenty-one years.
property committed with violence; 433 (including 332 cases of simple larceny) with offences against property committed without violence; 4 with malicious offences against property; 5 for forgery, coinage, and uttering base coin, and 18 for various misdemeanours. Of 394 persons convicted, 2, against whom sentence of death was recorded, were transported for life; 14 other offenders were also transported for periods above ten and under fifteen years; 30 for periods above seven and not exceeding ten years; and 23 for terms of seven years, making 53 transported. None were sentenced to imprisonment for periods exceeding two years; 2 were imprisoned for a period not exceeding two years; 31 for periods exceeding six months and not exceeding one year; and 277 for six months and under; and 2 were whipped: 1 received a free pardon. Of the 154 persons acquitted, 107 were found not guilty on trial; in the remaining 47 no bill was found; and in 8 instances there was no prosecution. Nearly one-half (275) of the total number of persons committed were between the ages of 10 and 22; or one-fourth (138) between 15 and 20, and one-fourth (157) between 20 and 25, which are higher proportions for these ages than the rest of England and Wales. The degree of instruction was ascertained in all but six cases: 117 males and 10 females could neither read nor write; 349 males and 45 females could read and write imperfectly; 14 males and 1 female could read and write well; 1 male and 1 female had received a superficial education. The proportion of uninstructed criminals on the county on an average of several years was 91 per cent.; in England and Wales 89.3 per cent.

Savings Banks.—There are eleven of these institutions in the county, and the number of depositors in 1841 was about 1 in 26 of the total population; but while the average amount invested by depositors in England was 52½ each, it was 36.6 in Wills, and as the proportion of depositors under 20 is only 1 in 30 (in England 1 in 37), the inference is that few of the labouring classes are above the average themselves of the savings-banks. The number of depositors and amount of deposits in each of the following years were as under:

<table>
<thead>
<tr>

Lending libraries of books are attached to 44 schools.

Thirty-six Sunday-schools, attended by 1440 children, are returned from places where no other school exists. Fifty-six schools, containing 2816 children, were both Sunday and day schools. The number of boarding-schools is forty-six, and the scholars are included in the returns. The total number of children observed as attending Sunday and day schools of all kinds is 51,530: in 1841 the total number of children in the county between the ages of 5 and 10 was 32,554, and 29,798 were between 10 and 15.

WIMBORNE MINSTER, a very ancient market-town in the eastern part of Dorsetshire, on the road from Salisbury to Poole, seven miles north of Poole, and 100 miles from London. It is supposed to have been a Roman station called Wimborina; and it is again mentioned as Vinburnam. A nunnery was established here in the beginning of the eighth century by the sister of Ina, king of the West Saxons, upon the site of which the present minster or collegiate church was built; and the grant of lands has been added to that of the church from it from Wimborne St. Giles's, in another part of the county. Wimborne Minster is pleasantly situated on the Stour, near its confluence with the Allen. There is a weekly market, a cattle market every alternate week, and two annual fairs. The town has little trade. With the exception of the minister there is nothing to indicate its former importance. The nunnery was destroyed by the Danes, when the establishment was converted into a college of secular canons, consisting of a dean, prebendaries, vicars, and other officers, which continued to exist until the dissolution, when the revenues were vested in the crown. Some of the lands were set apart by Queen Elizabeth towards the support of the grammar-school, originally founded by the Countess of Richmond, mother of Henry VII, in 1507, though now called after Queen Elizabeth. In the reign of Charles I. the possession of the school and church were vested in governors, who were to provide for the service of the collegiate church and the maintenance of the school. Parts of the minster were built upon after the Conquest. It is a cruciform structure, 106 feet in length, and consists of a chancel, nave, choir, and side-aisles, a transept, and three porches. The minster once contained ten altars of altabaster and other costly materials, and the whole structure was particularly splendid. There are two quadrangular towers, one at the west end, and the other, now surmounted by a very lofty spire, at the intersection of the cross: the whole edifice is particularly deserving of notice. The cathedral

3 K 2
service, on Saturday evenings and holidays, and has not been discontinued many years. The minster is a royal free chapel, and a peculiar in the diocese of Salisbury. The duties are performed by three incumbents appointed by the corporate body above mentioned. Several royal and noble persons have been interred here; among others King Ethelred, who was slain by the Danes in 972; also, the duke and duchess of Somerset, the maternal grandfather and grandmother of Henry VII. There are two ancient hospitals for poor aged persons. The entire parish contains 11,980 acres, and there were 4,326 inhabitants in 1841. The parish comprises Wimborne Minster (pop. 1687), tything of Holt (1313), tything of Leigh (574), and manor of Kingston Lacey (752). There are several hamlets in the parish.

WINCHESTER. [SOMERSETSHIRE.]

A WHEEL AND AXLE is a machine constituting a small windlass, and consisting of a cylinder of wood which is capable of turning on its axis between two upright posts of the same material, or between the ends of a cast-iron frame; a lever at one or at each extremity of the cylinder, is attached to an iron axle passing through the latter at right angles to its direction, and is furnished with a handle, which is parallel to that axle. The name winch is given to a lever or handle of this kind, and the word is supposed to be derived from the verb guincher, signifying, in old French, to bend in a curve. The lever, in a manner, is a cylinder, and the machine is used to raise a weight vertically, or to draw an object towards it; for which purposes the object is connected with a rope or chain which continually passes over the curve of the cylinder, and is turned by a man acting at the handle. Since the cylinder revolves while the handle, or the extremity of the lever to which it is attached, is made to describe the circumference of a circle, it is evident that the mechanical power of the machine is precisely that of the wheel and axle. [WHEEL AND AXLE.] When of a simple form it is employed to raise water from a well, and earth or any other material from the shaft of a small mine; and one of a complex nature is used, by means of a crank, to raise heavy packages from the ground to the upper part of a building.

When great weights are to be raised, the machine is usually fixed in a frame of cast-iron, which is rectangular on the plan, but its extremities or faces have the form of a triangle, or of a lever, or both. The cylinder of the machine is supported on a horizontal bar at the middle of each end of the frame, and to the cylinder is attached a toothed wheel which turns with it on the common axis: above this wheel and parallel to the cylinder is an iron axle which carries a pinion revolving with the cylinder, and causing the latter to rotate, the pinion itself being turned by means of the lever and handle at one or at each extremity of the frame. A machine of this kind is called a crab; and when a weight is to be drawn horizontally, or raised to the level of the cylinder, two wires are placed at any angle to one another; consequently when one man is pushing or pulling horizontally, the other is pressing or pulling vertically, and thus the operation of turning goes on with nearly uniform intensity; the first man working in the position of the other is working in the pulley, which is diminished by the difference between the two circumferences, and the weight is raised up through a height equal to the difference. Hence by mechanics, if 2R represent the circumference of the cylinder described by the handle of the winch in one revolution, the half sine of the difference between the circumferences of the two cylinders, W the weight to be raised, and P the power applied to the handle, we shall have, in the state of equilibrium, \[
\frac{r - r'}{2R} = \frac{P}{W}.
\]

The weight which may be balanced by a given power \( P \) will evidently be greater as \( r - r' \), or the difference between the radii of the cylinder, is less; and the difference of these, which may be called the tangent of the angle which is made by the handle with the vertical, is the mechanical advantage of the machine. The only disadvantage attending the machine when compared with an ordinary winch or capstan, is that it requires a much greater quantity of rope to raise or move the object through any given distance. It was first proposed in Europe by Mr. George Eckhardt, on the plan of a little machine which act on others at the circumference of a small wheel; and on the axle of this is a pinion with teeth, which work in those of a rack-rod. The axes of the wheels and pinions being let into the sides of a case of wood or iron, the revolution of the wheel produces the revolution of the rack; and one end of the case being fixed to the ground or against an immovable object, the extremity of the rack at the opposite end forces forward the body which it is to be displaced. Sometimes, instead of a rack, the machine is furnished with a wheel whose circumference is divided and cut in the form of a concave screw; within this screw is one of the convex kind, by which the revolution of the wheel and its axle is made to move in the direction of the latter, and thus to press before it the object which it is to be moved. This machine has however considerable friction.

The force exerted by a man in turning a winch vertically varies according to the position of the lever with respect to the horizon. When the lever, or that part which is perpendicular to the axle, is perpendicular to the ground, and the handle is at the highest or lowest part of the circle described by the end of the lever, the man either pushes the handle directly from him or pulls it directly towards him; and in each case he exerts a power which is estimated at twenty-seven or thirty pounds; but when the lever is in a horizontal position, the man either throws a great part of his weight on the handle to press it down, or he exerts his muscular force in a direct manner to pull it upwards; and the force exerted in these positions is estimated at 60 or 70 pounds. The force exerted in these positions have different values between these quantities in other positions of the winch; and the practice is to cause two men to work at the same time to turn the machine, one being at each extremity of the axle of the cylinder. The wires are placed at any angle to one another; and consequently when one man is pushing or pulling horizontally, the other is pressing or pulling vertically, and thus the operation of turning goes on with nearly uniform intensity; the first man working in the position of the other is working in the pulley, which is diminished by the difference which is met.
WINCHESTER, an ancient city, a municipal and parliamentary borough, and the see of a bishop, in 51° 4' N. lat., 1° 19' W. long., is 624 miles south-west from London by the road, 64 miles by the South-Western Railway, and 128 miles from the railway station at Southampton.

The town in 1154, the metropolis of England; its origin is lost in the fables of tradition. The Britons are said to have called it Ceur Gwent, or the White City; the Romans by whom it was first subdued named it Venta Belgarum; the Saxons, who were the next possessors, named it Wintaneccester, which has become Winchester; in Latin deeds and by the Latin writers it is called Wintuncia.

Winchester appears to have flourished under the Romans as long as they remained in the island. The modern town is situated on the site of the ancient city, which, as it is stated above, was divided by the Britons. In 519 it was conquered by Ceretic the Saxon, who afterwards made it the seat of his government, and it continued to be the capital of the West Saxon kings till Egbert, the first king of the whole heptarchy, was crowned there, and then it may be said to have become the metropolis of England. Though sometimes plundered and in the possession of the Danes, it continued to be the capital of successive Saxon kings till 1016, when Sweyn, the Danish king, met his death here. But when Robert, one of the first of the Norman kings, became king in 1052, Winchester became the seat of his government. After his death a fierce struggle ensued, and England is said to have been ultimately divided into two kingdoms; London became the capital of the Saxon; Robert of Normandy, afterwards Edward Ironside, till Edmund's death in 1016, when Canute became sole king and Winchester sole capital.

After the Norman conquest Winchester continued to be the capital, and during the reign of Henry I. the ancient Saxon borough and its suburbs were surrounded by strong walls; was defended by a castle built by William the Conqueror on the west, and another, subsequently erected for the residence of the bishop, on the east; there was an extensive palace and numerous mansions of the nobility; a cathedral of the Norman work; and a large number of churches; the suburbs extended a mile from the walls in every direction; to the north, on St. Cross, to the south, on Week, and to St. Magdalen's Hill on the east.

The reign of King Stephen when Winchester began to fall from its high estate. While Stephen was a prisoner in Gloucester Castle a contest commenced between his queen and the Empress Matilda, aided by their respective partisans, which was carried on for several weeks in the streets of the city, and ended by the burning of the whole of the town north of the High Street, the royal palace, the abbey of St. Mary, Hyde Abbey, and about forty churches, were burnt down or laid in ruins. The death of Stephen was the signal for 133 unrebated and unmeditated warfare. Henry II. resided much at Winchester; he rebuilt the palace, and, to a considerable extent, renewed the city; but London seems to have found more in the eyes of subsequent kings, and Winchester lost its dignity as capital of the kingdom.

In the contests between Henry III. and his barons, Winchester suffered severely, both parties alternately gaining possession of its castles, and carrying on the work of destruction in the city. From this time Winchester, though part of the property of the Crown, was never more than a suburb of the growing city of London. The church of the cathedral, and other ecclesiastical and scholastic establishments, seems to have declined rapidly. In the reign of Henry VI. a petition was presented to the king, which stated that 597 houses were uninhabited and seventeen churches were shut up. The corporation, previous to the Municipal Reform Act in 1835, was styled 'the mayor, bailiffs, and commonalty of the city of Winchester.' The governing charter was 30 Eliz., and the corporate body consisted of a mayor, six aldermen, twenty-four men, and an officer, the mayor, the number of burgesses, or municipal electors, in 1557 was 817. The total annual expenditure of the borough in 1841-42 was 2163l. 17s. 6d., the chief items of which were—494l. 15s. 1d. for police and constabulary; 10s. for salaries and other allowances to municipal officers; 300l. for gaol, and maintenance, &c., of prisoners;
Henry in 438, the termination was 1884 (4 James 11.). A new charter was granted September 15, 1688 (4 James 11.), which re- cites the surrender, and then renews the franchises in nearly the same terms as the charter of 1638; this charter was confirmed and extended by another, Nov. 6, 1688.

The bishop of Winchester extends to Hampshire, Surrey, Guernsey and Jersey, and two or three benefices in Wilts and Sussex. The net yearly income of the bishop, as given on various dates for three years prior to 1831, was about £50,000. By the same average the net income of the whole of the benefices in the bishopric was 143,614/-, and the annual stipends paid to curates amounted altogether to 19,856/.

The gross yearly income of the dean and chapter of Winchester was by the same average £15,334/., and the average yearly payments charged upon and paid out of this income was £2700; leaving a net income of £12,783/.

The town has no trade of consequence, but the statements of population show that it is in a state of gradual improvement. Being the centre of an agricultural district, it has a good corn-market, which is well attended. Few cattle are sold, but there is a large annual sheep-fair. Several improvements of late years have been obtained for the improvement of the city and suburbs, most of which relate to the navigation of the Itchen.

Winchester Cathedral, which is one of the largest cathedrals in England, is in many respects one of the most interesting. The entire length of the building is 465 feet. From the west entrance to the choir is 356 feet; the length of the choir is 135 feet; and the Lady Chapel, at the east end, is 86 feet, which makes the total length. As a distinct part, the nave is 220 feet long, 86 feet wide including the aisles, and 70 feet high; the choir is 60 feet long, and 49 feet wide. The dimensions of the transepts is 186 feet. The square of the tower is 48 feet by 50, and the height is 1384 feet, which is only about 36 feet above the roof: of course it has a low and squat appearance, and was perhaps not intended to contain bells, but only as a symbol of the church. The effect of the height of the tower is increased by the height of the nave, which is 70 feet. There is no other part of the church which the height of the nave, the stricken with their wide circumference and massy appearance, and his admiration is perhaps rather increased than diminished when he learns that they are the Saxon or early Norman pillars inclosed in a Gothic casing of clustered columns. Of the 28 boy s, 27 have been converted by intersections into pointed arches, and the original Saxon nave thus made Gothic.

The original structure of Winchester Cathedral, which is the finest and oldest in England, converted to Christianity, was destroyed by the pagans in the 1st, and rebuilt by one of his successors, the Christian Kingin. Some of the most substantial walls and pillars of the present structure were erected by St. Ethelwald, bishop of Winchester, who lived to finish it, and which is said to be W. in 690. In 1079, having been much damaged by the Danes, it was repaired by Bishop Walekyn, who built the present tower, with part of the nave and transepts, and in 1083 re-dedicated the church to St. Peter, St. Paul, and St. James. The choir was rebuilt about a century afterwards by Bishop Godfrey de Lucy, and the whole of the west end was repaired and renewed by the successive bishops Edynford and Wykeham. The grandeur of the west front is due to Wykeham. The part between the tower and the Lady Chapel was added in the early part of the sixteenth century by Bishop Fox, whose statue, under the canopy, terminates his improvements to the east. There have been many recent restorations and repairs of the cathedral, which have been executed with good taste, at the cost of many thousands of pounds.

Among the monuments in the cathedral may be mentioned the tomb of William Rufus, of plain grey stone, without inscription, in the choir; the six mortuary dees of wood, carved, painted, and gilt, in which Bishop Fox deposited the remains of Saxon Kings and other distinguished persons, which he transplanted from the deep lead coffins in which they had been buried; and especially the beautiful chantries or oratories of the bishop Edynford, Wykeham, Beaumont, Wyntfe, and Fox.

Over the altar is a large painting by West of the slaying of Lazarus from the Dead, which is considered one of his best works.

The present establishment of Winchester College, which, after the dissolution, was dedicated as a chantry for prayer for the souls of King and Queen, the bishops and abbots of Winchester, and all the bishops of the diocese, is a most imposing edifice, consisting of four stories, six minor canons, ten lay clerks, or singing men, eight choristers, and other members. The last prior was William Basing, who was made first dean, and died in 1549.

Winchester College (St. Mary's College), which lies next the cathedral, was founded by King John, at whose instance the Bishop of Winchester, William of Wykeham, in 1387, on the site of the "grammar-school of Winchester," at which he had been educated. The college was founded and endowed by Wykeham as a preparatory college to New College, Oxford, which he had founded, and by which he had bequeathed to the college of Winchester the dean and chapter of Winchester and the advowson of Winchester College, to supply vacancies which may happen in New College during the subsequent year. Besides the scholars on the foundation there are generally upwards of 100 boys not on the foundation, who are lodged in a spacious quadrangular building contiguous to the college.

The entrance to Winchester College is by a gateway into an outer court, which leads by another gateway into a large quadrangle, which is formed by a long building, 100 feet square, and is 32 yards. The chapel and hall form the south side of this court; they are beautiful specimens of Gothic architecture, worthy of the founder. The cloisters adjoin the chapel, and form a square, each side of which is about 120 feet.

The line of the centre of the area of the cloisters is the library of the college, which was originally erected as endowed as a chantry by John Promont in 1400. The chapel was removed to the Reformation, and the building remained unappropriated till about 1623, when it was converted into a library by the liberality of Dr. Pinke, warden of New College. It is a handsome building, corresponding in style with Wykeham's original erections in the school-room, which was built by a subscription from the Wykehamists in 1697, at a cost of 3253/., and is pointed arches in general, the most beautiful of its kind. Over the entrance is a fine statue of Wykeham, by Caius Gabriel Cibber, the father of Colley Cibber, who modelled and cast at his own expense, and presented to the society.

The entrance hall is a fine room 50 yards square, and the done stone.

The manor of Wolcot Castle are at a short distance south-east from the college. This castle, once the residence of the bishops of Winchester, was built, in 1386, by Henry deBlis, brother of King Stephen and John of Gaunt. it was inhabited by the descendants of the Saxon kings. It was a place of great strength till it was demolished in the reign of Henry II. It continued to be the residence of the bishops till it was demolished by Cromwell in 1646.

The village palace, begun by Bishop Morle, in 1654, and completed by Bishop Trelawny, was suffered to go
The Cross, in the High Street, is supposed to have been built about the beginning of the fifteenth century. It was the subject of the famous poem of St. Germain, founded by King Arthur. The Cross was on an octagonal base of five steps. The circumference of the lowest step is 49 feet, and the height is 43 feet. The cross consists of three tiers of Gothic arches, and it is built in the quaint niches and canopies.

Winchester Castle was on an octagonal base of five steps. The circumference of the lowest step is 49 feet, and the height is 43 feet. The cross consists of three tiers of Gothic arches, and it is built in the quaint niches and canopies.

Symonds's College (properly Christ's Hospital) was, as the ascension over the entrance gates, founded in 1607, by Sir Symonds, a native of Winchester, and afterwards a career of the city of London. The endowments are held by his executors, a master, a matron, and four

The Chapel of Winchester Castle, which was a building detached from the Castle, and at a short distance, was not a public library and reading-rooms. The chapel is very beautiful, and it is to be regretted that it is divided into law-courts, with jury-rooms, and reading-rooms, of statutes, of which the Society of the University is the parish church of St. Swithin, built by King Henry III. on the old postern of St. Michael, or King's Gate. The Guildhall, or Town Hall, in High Street, was built in 1712. The County Gaol is a block edifice, the front of which is a handsome and well-shaped structure of stone, built in 1846. The City Bridge, over which the canals cross, he was built in 1710. A statue of Henry III. was erected in 1759. The north wing was added a few years afterwards.

It is supported by voluntary subscriptions. The School Schools of Winchester are conducted on the proviso that none of the students shall be allowed to attend any other school than the School Schools of Winchester. They are supported by voluntary subscriptions.

St. John's House, which is the principal standing-room and assembly-room, is on the site of St. John the Baptist. There is a small theatre for the amusement of the students. The Hospital of St. Cross, about one mile south from Winchester, was founded and endowed in 1159 by Henry II. It was a perpetual reversion for poor men past their strength, and for 100 old women. As the charity grew in the 16th century, the church added a glass of ale and a small sum to persons who call at the hospital. The school is very useful, a cathedral in miniature, and the building which remain are a specimen of the architecture of the period of Henry II.

In 1735, in his eighteenth year, he went to Berlin and studied at the Academy there. During this time, he walked to Hamburg to attend the sale of the books of the celebrated Fabricius, and to buy some good editions of the ancient classics. The money for the journey and the purchase of the books he begged of the clergy, and, in 1735, about 120 books were bought in Hamburg. He lived in the Holdorf street, at Dresden, and in the opening of 1738, he entered the university of Halle, with the intention of studying theology. He remained two years at Halle, and found that the study of theology did not suit him. In 1741 he procured a situation as tutor in a private family at Oppenheim, in Hesse in 1742, he procured a situation at Heimert, near Heilbronn, where he commenced the study of general history, and is said to have read Bayle's "Historical Dictionary" twice through. In 1743 he was appointed Conrector of the school of Heß-"ton, a miserably paid post but it did not damp the courage of Winckelmann. He seldom went to bed; he used to sleep on a bench wrapped in a foul cloth; devoting what time he could spare from four in the morning until nine at night to the study of ancient literature and history. In 1746, when he was in this situation, he inspected the Graf von Buxan for a situation in his library at Nöthemitz, near Dresden. The place of librarian was engaged, but the court offered Winckelmann that of secretary of the palace of the Elector of Saxony. He was sent as secretary to Dresden, and the attractions of the great gallery there, induced him often to perform the journey from Nöthemitz to the Saxony capital, where he became acquainted with artists, and he endeavoured to become one himself, but to apply himself to the study of numbers. He finally decided to resign his situation and devote himself to his history and theory. In his ramblings in the gallery he formed three valuable acquaintances—those of Oeser, the painter, and of the distant Lepart and Hausdorff. Winckelmann, however, after much reflection, decided against the plan, and so not a single position was offered him by the Saxony court.

The first fruit of these advances was his able work entitled "Reflections upon the Limitation of the Authentic German Art" and the "Nachahmung der geschichtlichen Kunste," published in 1746. Of the ten copies only five were printed, and it was a library copy, and remained in the hands of the author, and Winckelmann, and Lepart, and Hausdorff, with a person of two hundred and eighty-six, granted by the sector of Saxon for two years.

The book on which he went to Mergas and the "Liberian" in the shape of a cabinet was printed in 1746, and he was published the "History of Wine" in 1746. Of the ten copies only five were printed, and it was a library copy. In 1747, he published a new book on the same subject, the "History of Wine" in 1747, and it was a library copy.
Winckelmann's chief work is his 'History of Ancient Art,' but it is very incomplete, as he himself was aware; nor can it be looked upon as any more than the Germann edition prefixed to the first edition of the 'History of Ancient Art,' by Feis, and the German Dresden edition of Winckelmann's complements, in eight volumes. Angelica Kauffman also painted his portrait, an etching of which is prefixed to Kinnaldy's "History of the Arts of Antiquity" ('Renaissance-painting of the Antients').

sation of a wind would be experienced. The tides which take place in the atmosphere by the attractions of the sun, moon, and planets on the particles of air giving rise to differences in the heights of the vertical columns, they must necessarily cause inequalities of pressure in horizontal directions, and thus produce winds or currents of air; but it has been shown by La Place that these currents are scarcely sensible; and such attractions are by no means adequate to account for the wind which are observed on the earth's surface.

The phenomena and causes of the great currents of the atmosphere have been already described and explained (see the references at the end of this article); therefore the present work shall consist after this time in seeing how the land-breezes and sea-breezes which occur diurnally on the coasts and in the islands of the tropical regions, and the periodical winds which are observed to prevail in some parts of Europe. The first are most probably caused by the inequalities of the sun's heat on the land and water; and both, by the tendency of the atmosphere to preserve a state of nearly uniform density. It is well known that the sun's rays in passing through a glass vessel filled with a transparent fluid communicate to the latter very little heat, and that if the fluid be rendered opaque, or an opaque body be introduced into the vessel, the temperature is sensibly raised in consequence of the caloric combining more readily with the opaque than with the transparent material. Now, on the other hand, the air which remains in the space above the ocean is more rarified, and temperature higher than that of the neighbouring ocean: the atmosphere above it consequently becomes rarefied, and from about 9 a.m. the air from the sea flows towards the land, to occupy the partial vacuum there produced. In proportion as the wind becomes greater the force of the sea-breeze also increases, and this continues till 2 or 3 p.m. After that time the temperature over the land diminishes more rapidly than over the sea, as the heat more readily dispenses itself from the land than from the sea, and the sea-breeze ceases. During the night, the land continuing to cool, the air over the sea becomes comparatively warmer and more rarefied, and a breeze from the land takes place: this wind augments in force till near sunrise, when the temperature over the land becomes greater than over the sea, and the wind blows from the sea as at first. These land-breezes diverge in every direction towards the coasts of the tropical islands from the high lands in their interior. Mr. Redfield modifies the hypothesis above stated by assuming that when the stratum of air lying on the surface of land which ascends towards the interior of a country becomes rarefied by the sun's heat, it is forced by an excess of pressure at its lowest part to move up the slope; and that the air thus rising, and the surface acquiring greater density, its gravity causes it to descend towards the sea. (Amer. Journal of Science, vol. xxxiii, No. 1.)

The eolian winds (so called from διαοιν, annual) is a description given to those which every summer blow during six weeks over the countries bordering the Mediterranean, but it has since been applied to other periods as winds, which blow on the coast of Holland. They commence in the Levant about the middle of July, rising at 9 A.M. and continuing during the day-time only: the direction of the current of air is from north-east to south-west; and it is probably caused by the rarefaction of the atmosphere nearly under the tropic of Cancer, consequent generation of the heat of the sun at that time, and the pressure of the sea-breeze from the sea-breezes diverging towards this point. The sea-breezes from the sea increase during nine days only. (Nat. Hist., lib. ii, e. 47, &c.)

Winds depend on a great measure on variations in the temperature of the atmosphere; they are therefore not subject to any known laws, and, except in a few cases, their periods are not due to any particular cause. They are observed however, in addition to what has been said respecting the trade and other regular winds, that those which prevail in the temperate zones are probably the result of currents proceeding about the earth from the tropics. Mr. Issel has described the 'Chimie' Magazine for September, 1837, that when the sun is on the meridian of any place, as London, situated beyond those regions, the currents of heated air which proceed from the point vertically under him must arrive at that place from the south earlier than at any other place eastward or westward of it, in the same parallel of latitude.

But in proportion as the sun becomes successively vertical at different points westward of the meridian of London, the currents of air, in describing great circles of the sphere, arrive later, and in a direction from the westward of south; and when, during the summer, the point of intersection of the sun's rays and the equator is about 60 degrees west of London, that is, in the evening, they arrive nearly from the west. At midnight, when the sun is on the meridian under the horizon, the current of air passing over the north pole is felt as a north wind; and in the opposite season, when the point of the point of intersection of the sun's rays and the equator is about 60 degrees east of the meridian of London, that is, in the morning, they arrive nearly from the east. By the influence of currents which proceed from the pole to the equator in order to supply the place of the heated air which descends from the surface of the earth between the tropics.

The sun is not the sole cause of the currents which are observed in the atmosphere, for they often arise from the condensation of the aqueous vapours which are constantly rising from the surfaces of rivers and seas. Such vapours, by the same means as have been described above, are accompanied with them a quantity of calorific, which escapes on arriving in a region where there is less of this element than at the surface of the earth; and the vapour being then reduced to a state of water, a partial vacuum is produced, into which the air, driven by the rarefied or heated air, is conveyed, at the same time, by the wind the drops of water, and thus the region in which the rain is falling is sometimes warmer than those which surround it. Rain-winds are produced by the air which descends to the ground under the globules of water. As these globules are engaged from the globules on the latter striking the ground, are then driven off, with considerable force, in every direction from the place where the rain is falling. In explaining the cause of the cold and dry state of the atmosphere in the north-western part of Europe, it is usually accompanied a north-east wind, M. Monge observes, in the 'Annales de Chimie,' that the currents of air from that quarter, having passed over mountain-lands, experience, from their elevation, a diminution in the general atmospheric pressure, in consequence of which they lose part of the water which they held in solution, and thus they acquire greater specific gravity. Hence, in advancing over the lower lands of Poland and the north of Germany, the weight of the atmosphere which is increased; the moisture then rises in the barometer tube, and the upper strata of air, whose temperatures are lower than that of the air near the earth, descend towards the ground. The air in these strata, being far from the point of condensation, carries also a great deal of water in the lower regions of the atmosphere; and this, by carrying off calorific, contributes greatly to produce the degree of coldness which is experienced.

All mountain districts are subject to sudden and violent gusts of wind from the intertwinings which the ridges of high land create to the general currents of the air; but that which is called the Helm-wind at Crossfell in Cumberland is one of the most remarkable of these phenomena. It occurs at uncertain times between the middle of August and October. In the last week or month of the autumn, the Helm-wind, though it is usually, though rarely, in summer. It is stated that, when not a breath of wind is stirring, and scarcely a cloud is to be seen, there is suddenly formed a line of clouds, called the 'Helm,' extending nearly north and south along; the top layers of air being detached; and nearly parallel to this, another line of clouds, called the 'Bar,' forms itself; the first of these lines of clouds is well defined within its western, and the other at its eastern edge; and the lines unite together at their northern extremity, forming an elliptical space whose length, in the north and south direction, varies from 8 to 30 miles, and its breadth, in the east and west direction, from half a mile to 4 or 5 miles; the highest point of the ridge of clouds is at the last of the first line of clouds. In a few minutes after the formation of the Helm a violent wind begins, within the space between the clouds, to blow from some
eastern point of the compass, but generally from due east to due west: its force is such as to break trees, disperse the grain in stacks, and overturn a cart with its horse: it continues frequently for nine successive days, and its motion is said to resemble that of the sea in a violent storm, but it is seldom accompanied by rain. No satisfactory hypothesis has yet been offered to account for the phenomenon; but that which seems most probable is, that the air from the elevated portion of the country, in the latitude of the humberland, has ascended the summit of the mountain and there condensed, descends from thence with great force, by its gravity, into the district at the foot of the western escarpment. (Rev. J.Watson, in "the British Association," vol. iv.)

If we contemplate the influence of the winds in the economy of human life, we shall find them highly beneficial. Though storms are often destructive to life and property, both at sea and land, yet they contribute greatly to the fertility of the soil. The alternate drying and moistening of the earth, occasioned by the alternation of nitric and exhalations: the winds impel the clouds from place to place, and thus diffuse over great tracts of country the rains which contribute so much to fertilize the ground. Wind is extensively employed in giving motion to machinery; and, till the recent application of steam, it was the only power by which ships were transported across the ocean between different regions of the earth. [ATLANTIC OCEAN; MONSOONS; TRADE-WINDS; WHIRLWINDS.]

WINDAGE is the quantity by which the bore of a gun, mortar, or shell, exceeds that of the shot or shell which is to be discharged from it.

The deviations of shot and shells from a truly spherical figure, and the inequalities in the bore of the ordnance, were formerly considerable; and on these accounts it was necessary to have a sufficient clearance between the assumed diameters of the ball and bore, in order to ensure the possibility of making the former enter into the latter: it followed from the greatness of this clearance, which in the British service was about one-twentieth of the diameter of the bore, that much of the fire-gunpowder escaped without producing any impulse on the shot, and that the latter was driven from one part of the surface of the bore to another; so that, on being expelled from the gun, it deviated widely from the intended direction of its flight.

For the year 1775, when Dr. Smellie made his famous experiments on the velocities of shot, the disadvantage attending a great windage was known, and a diminution of its quantity was proposed: but the precise amount of the force lost by it was not ascertained till the years 1784 and 1786, when experiments were made for the purpose, in part of determining that important circumstance. From these, it appeared that about one-fifth of the charge of powder was lost by a windage equal to '06 inch, or of the calibre (== 2 inches), and a further loss, amounting to between a and of the charge, was occasioned by an increase equal to one-tenth of an inch above the former windage.

The correct geometrical forms which are now given to the balls, and also to the bores, permit the windage to be reduced much below its former degree; and the following table contains, in fractions of the calibre, that which is now allowed in this country for the shot and shells appertaining to some of the heaviest ordnance:

WINDAU is a seaport in Courland, at the mouth of the river Windau, which rises in Wilna, traverses Courland in a south-westerly direction, has a fall of 21 feet near Goldingen, and empties itself into the Baltic at Windau, where it forms a small harbour; but there is a capacious roadstead, well secured by sand-banks which break the swell of the sea. Windau is a small ill-built town, with unpaved streets; there is an ancient castle, situated on an eminence, the church of which is now the parish church. The population hardly exceeds 1200 or 1300, mostly merchants and shopkeepers. There is a productive fishery at the mouth of Windau. About 100 ships commonly visit the town, which take in cargoes of flax, hemp seed, hemp, hempseed, corn, timber, raw hides, tallow, and salt meat.

Windau appears to have been formerly a place of more importance than at present. The Estates of Courland used to meet here. (Hassel, Stein, Charnabich.)

WINDERMERE. [LANCASTER; WESTMORELAND.

WINDHAM, WILLIAM, was born on the 3rd of May, 1750, in Golden Square, London, and was the only son of Col. William Windham, of Felbrigg in Norfolk. The Windham family are an old and respectable one, and it is thought, from a discovery of their arms, that as early as the twelfth century, when Mr. Windham's ancestor purchased the property at Felbrigg, Mr. Win-
id himself was then seven for a year to the University of Glasgow, where he applied himself with great diligence to the study of mathematics, a study for which he retained his fondness and which he pursued with success in his later life. In September, 1767, he was entered as a gentleman-commoner at University College, Oxford. He left Oxford in 1771, having in the meantime refused an offer from Lord Townshend, an intimate friend of his father, to be appointed to be his secretary, and having been appointed to be with him to Ireland as his private secretary. At this period of his life so marked was the future statesman's indifference to politics, that, as we are told by Mr. Amyot, his biographer, on Mr. Windham's own authority, it was a standing jest that 'Windham would never know who was prime minister.'

On leaving Oxford, Mr. Windham went abroad. In 1773 he joined an expedition of discovery then being undertaken by Commodore Phipps, afterwards Lord Mulgrave, and afterwards discovered the north pole. When he returned he was appointed to land on the coast of Norway, and to keep the expedition.

Mr. Windham's first appearance as a public speaker, and in connection with politics, was at a county-meeting at Northwich, where he was paid a subscription in order to attend on a subscription in aid of government, for carrying on the war with the American colonies. Lord Townshend having proposed, and the Hon. Henry Hobart, brother of the Earl of Buckinghamshire, having seconded the proposal of a subscription, Mr. Windham came forward spontaneously to oppose it, and to denounce the conduct of the American war. Two years after, the interval having been passed by Mr. Windham almost entirely abroad, the memory of the speech led to his being put in nomination in the House of Commons, for the borough of Norwich, in the general election of 1780. He happened to arrive at Norwich, on his return from abroad to Felbrigg, being ignorant of the fact, and which had been made of his name, by the interest of the celebrated Lord Hardwicke, whose son and Burke were leading members. His political sympathies were with Burke and Fox, and generally with the section of the then opposition which owned Lord Rocking- ham for its leader. On the formation of the Ministry of 1782, which John- son and Burke were leading members, Mr. Windham received the appointment of under-secretary to the earl of Northington, who was appointed lord-lieutenant of Ireland. Mr. Windham occupied his office in August. The reason of his resignation was stated in Hardy's 'Memoirs of the Earl of Charlemont,' that the reason of his resignation was a distribution of patronage by Lord Northington in favour of the old court party, in opposition to the views of Lord Charlemont. When Ireland was in a state of storm, and the coalition ministry was itself at an end before the close of the year 1788. In March of the same year, Mr.
ceeding year Mr. Pitt dissolved parliament, and Mr. Windham again contested Norwich, and this time with success.

Mr. Windham made his first speech in parliament on the subject of the Westminster surtax, on the 4th of February, 1795. The particular motion was, to order the high bailiff to make an immediate return: it was opposed by Mr. Fox, who, although Mr. Windham replied, and he was followed by Mr. Fox himself, to the point on the "increase of the abilities they had witnessed." Mr. Windham was appointed one of the managers of the impeachment of Warren Hastings, the particular charge intrusted to the House was "the subsequent sacrifice of the people of the dominions of the Nabob Fyzoola Khan in 1774, after an invasion of his territories by the Company's troops, and the payment by the Nabob of the sum of 150,000/-, on ratifying the treaty." On the Regency questions which arose in 1798 out of the king's illness, Mr. Windham was a very loyal, decided and realistic man in favour of the hereditary right of the Prince of Wales to the regency, and against any restrictions on his power. When this parliament, Mr. Windham's first parliament, was dissolved in June, 1790, he had already acquired a ripe political reputation.

Mr. Windham was again elected for Norwich in the new parliament. In the division of the Whig party, which was shortly after caused by the events of the French Revolution, Mr. Windham was one of the large majorities. At the general election, which was brought on by the Duke of Portland, and zealously supported the war with France. In 1794, the Duke of Portland, Lords Spencer and Fitzwilliam, and Mr. Windham joined Mr. Pitt's cabinet, Mr. Windham receiving the appointment of Secretary of State shortly before declaring for peace in February, 1801, when he resigned, together with Mr. Pitt, Lord Loughborough, Lord Grenville, Lord Spencer, and Mr. Dundas, because the king would not consent to the measures for the relief of the Roman Catholics in Ireland which they considered indispensable to the success of the legislative union. During the seven years that Mr. Windham had been in office, he had introduced many useful reforms into the administration of the army. On the 10th of July, 1798, he married Cecilia, a daughter of Admiral Edward Lord Nelson. On the 5th March, 1807, when Mr. Windham had been returned for the county of Norfolk, but having been petitioned against, and having lost his seat for that county on petition, he had taken his seat for the borough of New Romney, for which he had been elected.

The new ministry again dissolved parliament; and, by the interest of Lord Fitzwilliam, Mr. Windham was now chosen for Higham-Ferrars. In the session of 1808 Mr. Windham strongly denounced the expedition against the Netherlands, and was a firm opponent of the fated Walcheren expedition. On the resignation of Lord Castlereagh and Mr. Canning, after the failure of the Walcheren expedition, and on the consequent offer of Mr. Perceval to Lords Grey and Grenville, which they ultimately declined, there was a prospect of Mr. Windham's return to office, which he contemplated with no pleasure. "I have not virtue enough," he writes to Mr. Amyot, to whose biographical sketch, prefixed to the Vaccine Institute, he speaks in such high terms, "to be indebted for this account, to wish the ministers out, at the risk of being one of those who may be called upon to succeed them. . . . If I could always be as well as I am here, if Downing Street were in Felbrigg Park, or a single mile from my village, I should think myself happy in it; but the being called upon to read and write, to consider and decide, when one is exhausted and worn down with one's duty in parliament, has something in it that hardly any advantages or gratifications can repay; and I am afraid my inabilities in point of health and strength are not got the better of, even in the two years that have elapsed since I was last in office." And again, "I have had letters, with copies of the correspondence, both from Grey and Grenville, who seem to think that the ministers will continue to go on, and I cannot but hope it: for, in the other event, I am sure I don't know what is to be done. . . . I feel but little stomach to return to office, unless I can have carte-blanche with every one, and even then I think myself be-devilled, that there is no restoring things to their original state." Ill-health had much to do with this disinclination for official life. He had been for some time past a constant sufferer from rheumatic complaints. In 1810, he found himself and even them "perishing" in the hip, which, having been neglected till then, caused him much alarm, and ultimately brought on his death. In July of the preceding year he had, on his return home after a meeting in the House of Commons, fallen dangerously near to that of his friend Mr. Frederick North, who was at the time abroad, and whose valuable library was thus threatened with immediate destruction, and had given most zealous assistance in carrying away
Mr. North's books, succeeding in saving about four-fifths of them before the house was consumed. During his excursion he fell and hurt himself in the hip; and this was the origin of the tumour. In May, 1810, it was found necessary that he should undergo an operation for the extraction of the tumour. The operation was performed on the 17th of that month; at first everything went on well, but about a few weeks afterwards came on a crisis, and he then grew daily worse, until the 3rd of June, on which day he died.

Mr. Windham has left behind him a reputation not so brilliant as those of his contemporaries, Pitt, Fox, and Burke, but generally as weighty, and not unworthy of the association. His was a refined and highly cultivated mind, and if his eloquence had not the power or force to make it, as Mr. Canning justly said, "the man commanding" they had ever heard in the house, it was "the most imposing." His political life was marked throughout by a high sense of honour; and if his opinions may in some respects have erred on the side of moderation, as for instance on the subject of Parliamentary Reform, which, first and last, he opposed, he had always the courage to avow opinions which placed him in opposition to those with whom he usually acted, and exposed him to popular disapprobation. He was an accomplished scholar and mathematician. Dr. Johnson, writing of a well-known gentleman, had told the story, "to which I shall not again till I come back to the regions of literature, and there Windham is "inter stellas lunas minores." In a word, Mr. Windham has been described, as the description has been generally adopted as appropriate, of a model of the true English gentleman.

His speeches have been collected and published in 3 vols. 8vo., with a Life prefixed, by Mr. Thomas Amoyt, who was for some years his private secretary.

The general name given to any machine consisting of a barrel, of a cylindrical or conical form, which turns between two points of support on a pivot at each extremity of its axis, or upon a pivot at one extremity only, the machine, by means of a rope or chain passing round the barrel, raises heavy loads or ships, or draws them towards itself. Thus the windlass and axle, the windlass by which on board of small ships the anchors are weighed, and even the capstan, are as many different forms of the same machine.

The mechanical properties of all these machines are those which have been described under Wheel and Axle, and in the two last the power of men is applied at the extremities of handspikes or levers inserted at their opposite extremities, and made in the axle or barrel to receive them. In the capstan, the axis of the barrel is vertical, the handspikes are in horizontal positions, and the men exert a continuous pressure against them while walking round; but in the machine to which the name of windlass is more particularly applied, the barrel is horizontal, like a winch and axle. In order to turn the cylinder on its axis, the men mounting on it plant their handspikes vertically in a series of holes formed at intervals for the purpose; then grasping them as high as they can reach, they pull towards themselves; when the cylinder is turned nearly a quarter round, the handspikes being almost in horizontal positions, the men throw upon them the whole weight of their bodies and by the weight the cylinder is still further turned. After this, the handspikes are drawn out of the holes in which now are in vertical positions, and the like exertions of muscular force and pressure are repeated till the anchor is weighed or the weight raised. The machine permits the power of men to be extended, in one position of the handspikes, in the most advantageous manner. In this respect it may be considered superior to the capstan: the lengths of the handspikes are, however, limited to about six feet, whereas those of a capstan may, in extreme case, be made as long as they please; and it may be added that the latter machine allows a greater number of men to act at once.

The vertical windlass, or capstan, was originally a short cylindrical column turning on its axis by means of levers or blocks, which is generally inserted in the ship, and which the perforations made to receive them at the top of the column; the pivot or axle upon which it turned entered, as at present, into the floor or deck upon which the machine was placed. It appears to have been first used, at least in Europe, on board of Portuguese or Spanish ships for the purpose of weighing the anchors, and it was introduced in the British navy in the time of Queen Elizabeth: its name is supposed to have been derived from 'capastante,' which in the Spanish navy is the name given to the machine. In its original form it was subject to a great defect arising from the trouble and delay which was caused by the necessity of raising the coils of rope on the surface of the cylinder when, after several turns, they arrived at its foot. For this purpose it was necessary to cease turning the machine, and to secure the rope or messenger, that the weight might not descend while the upper coils were being removed from the cylinder, or while the three or four lowest, which it was necessary to leave on, in order by their friction to hold up the weight when the fastenings by which the rope was secured should be cast loose, were raised to the top of the cylinder. After this, the revolutions of the machine recommenced. The removal of the coils from the lower to the upper part of the cylinder is called 'surging the messenger,' and the method just described evidently causes a considerable loss of time, which on ship-board may be an inconvenience of great magnitude.

In 1739 and 1741 the French Académie des Sciences offered prizes for the best 'Mémoires' on the subject of capstans, and several methods were in consequence proposed for constructing rope windlasses, so as to render the motion of the rope might raise itself on the barrel. In 1794 Charles Lalande suggested that the cylinder should be surrounded by a spiral projection of wood, like the thread of a wedge, the turns of which the rope might coil itself as the cylinder rotated, and thus continually rise to the upper extremity, from whence it might be afterwards removed by hand. The same astronomer also invented a species of pulley, which was afterwards generally adopted, and is still in use; it consists of an arm of metal capable of turning on a pivot near the lower extremity of the barrel; and as the latter revolves, dropping by its weight into a notch cut in the upper surface of a ring of wood or metal which is fixed to the floor or deck and round which it runs, or drawn up by hands, or drawn out by windlasses.

Capstans are now generally made, as in the subjacent figure: the axle or central part of the barrel, which appears at A, is a cylinder of oak, on the surface of which are cut openings, strong enough to admit six other of similar shape and of four inches each, called, like butresses; these are at equal distances from one another, and have their faces inclined to the axis so as to give to the part of the machine on which the rope or messenger is to turn a pyramidal or conical figure. The upper part, C, of the capstan, is cylindrical, and is called the drum-head, has notches on its inferior surface to receive the heads of the ribs; and on its convex surface are the holes a a, Sc. for the reception of the bars by which it is to be turned. The ribs, by the friction which they create, prevent the rope slipping on the bar, and the conical form allows the rope easily to ascend towards the upper part as it winds about the barrel. Pulleys similar to those above mentioned are shown at B, B, B.

Frequently the capstan is made to consist of two parts, each similar to that which has been described, and attached one above the other to the same vertical axle; one of them being on the quarter-deck, and the other on the main-deck of
WIN

W I N

The page contains a text about windmills, describing their components and how they function. It mentions various parts such as capstans, sails, windmills, and their actions. The text seems to be extracted from a larger document, possibly an encyclopedia or a book, discussing the mechanics and operational aspects of windmills. The text includes terms like capstan, sails, and windmill, indicating it is related to engineering or mechanical sciences.
ingly; and the construction as well as the expansion of a sail is actually effected by means of ropes fastened to it in three places or more. These ropes may be either drawn tight or relaxed as required; but for either purpose it is necessary that the mill should for a time be stopped; and as the stoppage is attended with great inconvenience, several methods have been devised for rolling and unrolling the sails while in motion. One of these, which was invented by Mr. Bywater, consists in the application, on each arm or whip, of a cylinder or roller to which the canvas is attached; the outer end of which is at the extremity nearest to the axle; the teeth of this wheel work in those of two other wheels, and the motion of one or the other of these being stopped, the cylinder rolls up or unrolls the canvas, being controlled by its action on the axle by the action of the sail. Several methods have also been proposed for equalizing the action of the wind on the sails of a mill, and they consist generally in the employment of a series of valves fixed in the framework of each sail. These valves revolve on pivots which run in grooves in the upper part of the frame. The plane of each valve is oblique to the lines in which the wind impinges on it, the direction in which the latter blows being supposed to be parallel to the horizon; and the whole is inclosed in a fixed cylinder having the same horizontal diameter as the other. The wind thus impinging acts upon the oblique surfaces of the boards about the interior cylinder on one side of the axis, while it is, in a great degree, prevented by the screen from acting upon the boards on the opposite side; these boards therefore meet with small resistance when, during every revolution, they come up towards the quarter from whence the wind blows. In horizontal mills one board may receive an impulse equal to that which the wind communicates to a sail of equal area in a vertical mill; but in the latter all the sails are acted upon equally at the same time. Mr. Smeston estimated that the power of a horizontal mill was only about one-fourth of the power of a vertical mill, the former only one or two can receive the impulse of the wind, and there is always, besides, some resistance experienced in returning against the wind. Mr. Smeston states that in one instance windmills were raised to a height of 120 feet. Whether this is the case, or whether the height of 120 feet is only an estimate, it is certain that the windmills were raised to a considerable height, and that the power of the horizontal mill is about one-fourth of the power of a vertical mill. It is a matter of great importance to the windmill to have the greatest possible power from the wind. The power of the latter is not more than three or four times as great at that of a horizontal mill. The effective power of the vertical mill is however so much greater than that of the other kind, that the latter is now seldom constructed.

For an account of Mr. Beaton's improved construction of horizontal mills, see Brewer's edition of Ferguson's 'Lectures,' vol. ii. The effective force of the wind in turning the great sails of a mill is investigated in the article WINDMILL.

WINDOW. Though almost unknown in ancient architecture, at least in the religious and other monumental structures of the Egyptians, Greeks, and Romans, which were not of a natty and pleasing description, and perhaps not of an ornament to public edification, and still less of a use to the orders of the temple. Gothic without windows would be as deficient in expression as Grecian architecture without columns. Grecian architecture, on the contrary, hardly admits wind-
even of mere architectural finish and the expression derived from it, doors and windows claim it in the first place. Unless decoration be bestowed upon them, instead of being features in the design, they will show themselves only as blemishes, and in proportion as ornament is applied elsewhere, the whole will become incongruous patchwork.

The principle to be attended to is so generally disregarded, and its being neglected has occasioned such a false and vicious system of architectural design, that it cannot be too strongly insisted upon, with a view to its adoption. New forms of most striking instances of the faulty practice of leaving windows mere naked apertures, while even excess of decor is affected elsewhere: hence his festoons, panels, pilasters covered with arabesques, and other things of that kind. In order to secure the general effect of the building when it has become more general to bestow some sort of dressing on windows, there is seldom that study given to them which could be wished. Either the dressings are meagre or tame and insipid, and the windows are not so much the architect's own. If ornaments, as patterns appropriated by him from the common stock, and applied perhaps nearly at random.

It is one very great advantage of the Gothic or Pointed style, that there the windows derive strong architectural effect, because they are near so many other parts, like the columns, transoms, and traceried inserted in them, mainly form the design and decoration; while the external mouldings and ornaments contribute to them only in a subordinate degree. Consequently, in those places where plain windows are necessary and more vacant spaces. Widely different is it in those styles where the ornamental design is confined to the mere exterior or framing of the aperture: therefore however they may be so decorated, the openings will never appear so suitable, or in a more perfect style, and the glazed, and the glazing of the windows will appear to be in want of adequate support. Such is the case with the windows of St. Paul's, where the apertures are filled in only with very ordinary glazing in small panes, and consequently lose all their effect, and are as much as sombre, dingy appearance; whereas in Gothic windows the glazing shows itself to be firmly supported by the mullion, and is never extended over such large broken surfaces, let the size of the window be what it may, as to produce an effect of lightness. In Lombard Hall, pirch, p. 324, and Osie: since we must here confine ourselves to windows in the Italian or modern style generally.

The same general principles, although not the same specimen, apply to doors and to windows, both being apertures in the wall of buildings; and it is well here to remark that, unless otherwise expressed, in speaking of them as features in architectural design, it is not the actual door or the glazed window which is understood, but the door, or a few windows as a whole, and the dressings around them, which last term is employed to designate the whole of the decoration bestowed on such apertures, or, in other words, the entire composition. As in the style now referred to doors and windows do not differ very greatly in their proportions, the same composition may, with slight modification, be applied to either purpose. There are however distinctions to be attended to, since both the proportions and decorations of windows depend in some degree on their situation or the particular story, and not so much on their being plain, as the same composition, or that immediately over the basement or ground-floor, requires to be marked by windows more highly decorated and of loftier proportions than the rest. For these the apertures are generally made from one square to another, and their height is something more than double their breadth. Those on the next floor rather less than two squares, and for the third they are made mezzanines—either a perfect square or very little larger than that of which the whole proportions or of the ground-floor, requires to be marked by windows more highly decorated and of loftier proportions than the rest. For these the apertures are generally made from one square to another, and their height is something more than double their breadth. Those on the next floor rather less than two squares, and for the third they are made mezzanines—either a perfect square or very little larger than that of which the whole proportions or of the ground-floor, requires to be marked by windows more highly decorated and of loftier proportions than the rest. For these the apertures are generally made from one square to another, and their height is something more than double their breadth. Those on the next floor rather less than two squares, and for the third they are made mezzanines—either a perfect square or very little larger than that of which the whole proportions or
tableau, whereby the general form of the skamandra, or dressing, becomes square headed; the chief difference between these two tiers of windows is, that those above have pediments (alternately angular and segmental), while the others have none.

It may not be improper to make some additional observations relative to the application of windows in architectural composition. Susceptible as they are of decoration in various degrees, windows do not, like columns, produce richness in proportion to the number and frequency of them; on the contrary, they require to be thinly spaced, and the greater the tendency towards the great number of those in the same range, but also the distance between the windows on one floor and those on the succeeding one. So far from a great number of windows and stories in a building being to give the desired diversity, they produce rather a contrary effect, by destroying that breadth and repose which are essential to such character. It is not the mere copying the forms and decorations of its windows that will give the effect of the Italian 'palazzo style,' since so very much of its character depends upon other circumstances, and on the proportions between the solids and voids. Hence, as Wielbeking has remarked, the general architecture both of London and Paris, even in the best streets, is very poor, owing to the windows being so numerous, closely crowded against wide pillars between windows in this country, as being suited only for a southern climate where shade is desirable; but narrow pillars are equally unsuitable for a northern one, since they cause a room to have a cold, unattractive and indifferent aspect. In the yet more modern cases, architects have attempted to lay down rules for proportioning the superficial area of the openings, or windows of a room, to the cubic space of the room; but besides being rather fanciful, this cannot consistently be followed in practice, because the size of windows and the need of light determined upon for one room must be adopted for all those in the same front—at least upon the same floor. Nicely of that kind would require that in a north or northern latitude, the relative proportion of window and wall should be very different from that adapted for a southern one, and must also vary according to the actual situation of the building with regard to others, since, with respect to light, it certainly makes a very great difference whether rooms are for a narrow or a wide street, whether the opposite buildings be lofty or low.

Nothing has yet been said on the various modes of decorating windows, and the members of which their dressings are composed. To begin, therefore, with what is perhaps the most original part of architectural decoration, we have first of all a simple border or architrave, similar to that represented in Doon, page 26, which figure also explains the mode of elbowing or kneesing the architrave, as it is called, so as to extend the lintel or horizontal part over the aperture, which makes the architrave consist of a single architrave, in order to give more importance to that part, and avoid too great uniformity of outline. The breadth of the architrave depends greatly upon circumstances, on the character of the general design, and on the taste of the designer: where the dressing consists of no more than an architrave, greater breadth may be given to it (nearly a quarter of that of the aperture) than where the sides are flanked by other members and the dressings forming a second or external architrave. In like manner the character of the architrave itself admits of great variety of expression: it may be merely a single plain surface surrounded by mouldings, as in the example just referred to, it may be divided into two, three, or even more facets, and may be carved with various mouldings carved; for its being a single border to the window-opening is no reason why it should not be a rich and effective one also.

The next step in the progress of decoration is to surround the lintel by a cornice, which is extended the full width if the architrave around the window be 'elboved,' or else rests upon consoles; nor is it by any means unusual to employ both eaves and cornices. After this, further decoration is obtained by introducing a frieze between the mouldings of the lintel and cornice, thus producing a regular entablature, which, however, may be variously proportioned and decorated. To convey an adequate idea of the very great diversity of design which is met with in regard to these few circumstances of composition, would require a very great number of examples, and those drawn upon a tolerably large scale.

The following remarks apply to the two examples from the Erechtheum and the Pantheon, represented in the article Doon, p. 86; but it must be premised that those cubs show only the general forms, without the less detailed and more enrichments. The fine specimen of Greek taste, and in perfect accordance with the columns of the portico—reduced in expression, and though simple in composition, even luxuriant in enrichment—is an instance of what, for want of more precise terms, I have termed 'the pure Greek style.' In the architrave, for in addition to the mouldings immediately surrounding the aperture, and constituting the architrave proper, there is an external border surrounding it, being continued over the lintel of the succeeding opening, and divided between that and the cornice. The architraves are not elboved, but the cornice is extended, owing to its being supported on consoles, which last are of different form, and not so long as those generally used. In the other example referred to, there are neither architrave nor consoles, but there is a full entablature, and though the frieze is narrow, such proportions suit a door or window of the kind better than a deeper one.

With these few elementary forms and principles great diversities may be derived as to the character, from almost the plainest to the most ornate. In the last-mentioned example, for instance, the external mouldings of the architrave, which are broader than any of the three faces, are very richly carved (although not so in the representation of the vault); and there have been many examples in which the mouldings are bold and numerous, while the rest of the architrave is a single plain and broad surface. In addition to the above, there are many other parts which enter into the composition of window-dressings, and among them is the proper relation of one to another in respect to the whole. Some critics have urged objections against the pediments to windows, as being contrary to strict propriety: hypercriticism of that kind might be directed against the general character and expression of the building, and the character and expression more or less depend. It is enough for us that the application of the pediment form to such purpose is so fully established that no idea of incongruity attends it, and that, considered with regard to its artistic effect, it contributes to variety in various ways. At the same time we cannot admit as legitimate more than two distinct varieties of it, namely, the angular, and the curved or segmental; for as soon as we begin to disturb the outline, we violate the principles of the style. 

Boiler pediments, scrolled-shaped ones, &c. are therefore to be put into the same category with twisted columns and other extravagances of that kind, which, so far from displaying invention, rather betray sterility of ideas, and the tendency to attach the least attention to anything which the least educated taste rejects as vicious. Even segmental pediments ought to be very sparingly introduced—perhaps only for the sake of variety, in alternation with angular ones, they being in themselves rather heavy in appearance. One great value of the pediment as a decorative feature of windows is, that its sloping lines contrast with those of horizontal mouldings, and occasion variety of outline in the general form of windows; and that such addition serves to distinguish and give due importance to the windows of the principal floor of a building, to which, in good composition, they are generally confined. In the Palazzo Farnese both the upper rows of windows have pediments; the first alternately angular and segmental, the other, the French cornice to the very great space over the windows, the numerous pediments do not seem to overload the design, as would be the case if the upper ones were to come nearly immediately beneath the superior cornice.

Window pediments are almost invariably supported on consoles, which, besides admitting of very great variety of detail, give rise to a mode of extending the dressing on the sides of the aperture by an external border, formed of a console, pilaster or console-jamb, the console being affixed to it; and which is either quite plain, or panelled and otherwise enriched, according to the degree of decoration aimed at. The annexed cut serves to illustrate both modes, one half of the window having merely a console, the other as
other instance just mentioned, and also in the front of the Clubhouse Chambers, Regent-street, though there are columns to the windows, there is a very sorry entablature to them—neither architrave nor frieze, but merely a plain lintel in lieu of them, without mouldings of any kind, which, besides being offensive and lumpy and heavy, look mean in what professes to be decoration of a superior kind.

That cryatides may be substituted for columns as decorations to windows, especially where an extraordinary degree of magnificence is aimed at, follows as matter of course. Indeed hardly can figures of that kind be introduced so well in any other way into exterior architecture; and though a front might be overdone by too much of such decoration, there is little need for cautioning against excess in that respect, there being no danger whatever of its being committed: on the contrary, we have hardly an instance of it.

When windows are round-headed, or arched, they are usually treated like arcades, with imposts and archivolt mouldings, either with or without keystones, plain or enriched; and they also admit of loftier proportions, since the arched head may be in addition to what would else be the height of the entire aperture: consequently so far from the form of the head in any degree diminishing the quantity of light admitted into a room, it increases it by being an extension of what the opening would otherwise be:—which, however, depends greatly upon circumstances, and whether the line of the impost or the crown of the arch would else be the top of the opening. Arch-headed windows are sometimes enclosed within a square-headed dressing, a mode of composition frequently practised by Bramante and others of his period, and of late again brought into use in Germany. It is one that admits of very great variety of design, and of much enrichment also, accordingly as the spandrels of the arch are left plain or filled up with foliage or other ornament. The ground-floor windows of the Pinakothek at Munich are of this description; and where it is desirable to keep up a degree of general uniformity between square-headed and arched windows in the same design, it may be done by giving square-headed dressings to the latter. (Fig. 2.) It is, in

We now come to another mode, quite distinct from any of the preceding, namely, that which consists in applying a small order either in columns or pilasters, with a regular entablature, sometimes with the usual architrave also surrounding the aperture of the window, at others not. And though some object to such microstyle compositions, as being inconsistent with the original purpose of columns, their impropriety is at least redeemed by richness and beauty. At all events, the impropriety is not so great as that of applying small orders successively to the different stories of a building, thereby rendering diminutive, parts which, if introduced, ought to be proportioned to the entire edifice; whereas, in the case of columns to windows, they show themselves to be intended only as decorations, and though really small, yet being distinct and independent features, instead of giving an air of littleness to the entire composition, they rather give greater dignity and importance to the windows. As to the actual effect produced by them, that depends upon the judgment and taste with which such decoration is applied. Windows of this kind are certainly not suited for any except asylar composition, since if there be also a large general order to the facade, while the columns to the windows look rather insignificant by comparison, there is too much of repetition and monotony, and the whole decoration seems nearly of columns of different sizes. Still worse is the effect when, as is the case with the Atlas Office, Cheapside, London, the building consists of more than one order, because then, as the windows must be large in proportion to those orders, the columns to the windows cause the others to look petty, and the whole to appear both crowded and confused—a defect most strikingly exemplified in the structure alluded to, nor is it at all diminished by the windows to both the upper floors being columnated. On the contrary, Barry's two clubhouses in Pall-Mall are truly beautiful examples in regard to windows thus decorated; for there they are treated in a most masterly manner, and applied with the happiest effect, and so as to produce a solicitous union of sobriety and simplicity with a very high degree of decoration. Instead of being mere copies, those windows are original and admirably studied compositions, beautifully and even elaborately finished, whereas in the}

P. C., No. 1736.

fact, not unfrequently done in the case of niches, if any internal decoration at all is bestowed upon them. There is besides, another, but exceedingly vicious mode of putting an arched window between columns and beneath a pediment, cutting away the entablature, and sometimes even cornice, so as carry the arch quite into the pediment.

Directly contrary to the preceding is that of enclosing a square-headed window within an arch, as has been done by Mr. Barry in the south front of the Travellers' Club, Vol. XXVII.—3 M
WIN 450

WIN

whereby it resolved to break this now, the columns
or, if there be none, the architrave is continued beneath
the aperture; or else the bottom of the window has a
distinct sill, either plain or moulded, and sometimes
supported on blocks or small consoles.

Though balustrades to windows were very seldom
employed beneath the architrave, or at the
architrave in Pescara and Fontaine's collection—there
are a great many examples of it in Pescara itself
and by Palladio, and also by ourselves for the principal-floor
windows in the Strand front of Somerset House, balustrades
are placed beneath both windows, and even in the window
not only beneath the windows, but on each side of them,
between their pediments and those of their order; whereby
confusion rather than richness is produced. Neither is it
advised to put balustrades, as Palladio has so often
done, beneath the windows without window dressings, since
this causes them to appear still more unfinished than they else
would. Still worse is it to apply them to mezzanine or square windows; for in such cases the balustrades and the
windows become quite out of proportion to each other, and
the whole effect is thereby most ungracefully lost.

One-halftone figures of the blemishes of Holkham, where it is accompanied
with another offensive solecism, namely, the putting a
corner above the window, leaving a space between the two, as
detrimental to effect; there is cut away—a
startling sort of economy, and quite contrary to the natural
principles of decoration which have been here pointed out,
and which teach us that embellishment ought to come
by finishing up the aperture itself, before any additional
work is done to it.

Circular windows, or oval ones, either oblong, as at
Somerset House, or upright, as at Buckingham Palace, are to
be avoided even for mezzanines and attics, since however
beautiful such forms may be considered in themselves, they have been so unfitted to the building as to appear
both fanciful and uncouth when applied to it.

Something yet remains to be said in regard to compound
or triple windows, which, besides contributing to variety in external design, are sometimes required by circumstance.

The kind of windows usually practised,
that familiarly known by the name of Venetian windows—
although there are very few instances of it in Venice itself
and divided by columns into three openings, the centre one of
which is both considerably wider and loftier than the other two, because, being arched, it has, in addition to
the arch itself, the depth of the horizontal entablature over
the columns and lateral openings, and from which the arch springs. When well composed, windows of this kind have
a peculiar rich and elegant appearance, besides the
importance they acquire from their greater size; but all de
pends on the taste shown in the particular design. If the
lateral openings are too wide—that is, half the width of the
centre one, the composition becomes sprawling and poor;
and if too narrow, by which means the columns be kept narrow, not much wider than the diameter of the columns themselves, the whole has with greater
compactness greater richness also. Kent has given us
some good examples of this kind, as in the Park front of
the House and the pedestal so high that the columns be kept narrow, not much wider than the diameter of the columns themselves, the whole has with greater
compactness greater richness also. Kent has given us
some good examples of this kind, as in the Park front of

Let AB, A'B', parallel to one another, represent the direc-
tion of the wind; WBX, W'B'X', also parallel to
another, two points is in all positions of the sail when
the pressure of the wind is made to move so that B', B
are in a line perpendicular to AB. Now, if it is supposed
that A'B' is the space described by a particle of air while B
will move to b (or B' to B') in the same direction—one direc-
tion of the wind; the lines AB and A'B' will, respectively, represent the velocities of the wind and sail in directions parallel to A'B', while BB will
be the velocity of the sail in the direction of this line.
Draw AC, perpendicular to WX or WX', produced
and meeting the one of the line in C; then AC and CO will
be respectively the velocities of the wind and sail perpen-
dicularly to the line WX or WX', and consequently AC will
be what is called the velocity of the wind in the sail.
Therefore, the pressure of a fluid being proportional to the square of the velocity, the pressure in the wind in the direction $A'C$ will vary with $A'C^2$; and this being resolved into the direction $A'D$ or $BB'$, will be expressed by $A'C$ or $A'D$, or $A'C$ sin $BB'$.

But $A'B'$ being constant, $A'C$ varies with sin $A'BC$; therefore the effective pressure of the wind will vary with sin $A'BC$ sin $BB'$.

Let $A'B'$ be represented by $a$, $BB'$ by $\theta$, $A'BC = \alpha$, and the expression for the pressure becomes

$$\sin^2 (\alpha - \theta) \sin \theta.$$

Making the differential of this expression equal to zero, and reducing, we have

$$\tan (\alpha - \theta) = 2 \tan \theta,$$

when the pressure is a maximum.

Draw $BX$ perpendicular to $BC$, so that $BX$ and $XY$ may respectively represent $\tan (\alpha - \theta)$ and $\tan \theta$; and let $AB'$, $BB'$ be respectively represented by $v$ and by $\theta'$, then

$$v = v' \cos \theta', B'X = v' \sin \theta',$$

$$XY = (2vX) = 2v' \sin \theta, \text{ and } BY = (3B'X) = 3v' \sin \theta.$$  

Assuming, draw $YZ$ perpendicular to $BB'$, or parallel to $A'B'$; thus:

$$B'Z = B'Y \cos BB' = 3v' \sin \theta',$$

$$YZ = B'Y \sin BB' = 3v' \sin \theta \cos \theta,'$$

and

$$B = v' - B'Z = v' - 3v' \sin \theta' \cos \theta.$$  

But by similar triangles, $BZ : \theta' : BB', B'A', that is, $v' \sin \theta' = 3v' \sin \theta \cos \theta,$

whence $v = 3 \sin \theta = 3 \sin \theta' \cos \theta' = \cos \theta.$

Multiplying each term by $v$, and for $\theta'$, the first term, substituting its equivalent $v^2 \sin \theta' + \theta' \cos \theta'$, we have

$$v^2 \sin \theta' + \theta' \cos \theta' = 3v' \sin \theta \cos \theta' = \cos \theta.$$

or $v = 3 \sin \theta = 3 \sin \theta' \cos \theta' = \cos \theta.$

We obtain this result by Mr. Smeaton, that the velocities of the sails at their extremities are often much more than twice as great as that of the wind. From several experiments which were made on a great scale by the same engineer, it was found that the effect is very advantageous when the inclinations of the axis, or the direction of the wind, with a section of the sail taken perpendicularly to the revolving arm at different distances from the axis, as were in the following table:

<table>
<thead>
<tr>
<th>Distance from the Axis</th>
<th>Velocity (m)</th>
</tr>
</thead>
<tbody>
<tr>
<td>At one-sixth of the arm</td>
<td>72</td>
</tr>
<tr>
<td>At one-third</td>
<td>71</td>
</tr>
<tr>
<td>At one-half</td>
<td>72</td>
</tr>
<tr>
<td>At two-thirds</td>
<td>74</td>
</tr>
<tr>
<td>At five-sixths</td>
<td>77</td>
</tr>
</tbody>
</table>

And this is his experiment.

Mr. Smeaton found also that when each sail is broader at the further extremity than near the centre, the effect is greater than when it has the form of a parallelogram; and that the most advantageous breadth at the extremity is one-third of the length of the arm.

There is a certain limit to the quantity of sail which a windmill can carry with advantage; and from Mr. Smeaton's experiments it results that, when the surfaces of all the sails exceed seven-eighths of the area of the circle described by each arm in one revolution, the velocity is diminished; probably from the want of sufficient openings by which the wind, after impact, may escape. Mr. Smeaton also found that the ratio between the velocities of windmill sails when unconnected with the machinery, and when loaded so as to produce the maximum effect, is variable, but, in general, that ratio is as 3 to 2. The velocity of the sails when the effect is a maximum varies nearly with the velocity of the wind.

The form and position of the sails remaining the same, the load or resistance when a maximum, varies nearly with the square of the velocity of the wind; and the maximum of resistance which sails of similar figures, and in similar positions, will overcome at a given distance from the centre of motion, will vary with the cube of the radius or arm of the sail.

WINDSOR, properly called New Windsor, is a parliamentary and municipal borough, on the banks of the Thames, in Berkshire, 22 miles from London. It derives its importance, and perhaps its origin, from having been a favourite residence. A party of the kings of England, into the Conquest. The Saxons kings had a palace at Old Windsor, called Windles-odra, or Windleshorn, from the winding course of the Thames in this part, and Edward the Confessor occasionally kept his court there as a distinct parish, about two miles south-east of New Windsor.

In the reigns of William the Conqueror and William Rufus Windsor Castle was a military fortress, and it is doubtful whether they used it as a residence. Henry I. enlarged and improved the castle, and held it in person from this time it was the frequent residence of the king, in consequence of which New Windsor received many marks of royal favour. From having been a chapel in the parish of Clewer, it was constituted a separate parish. Edward I. made it a borough in 1277, and it returned two members to parliament: probably through the indulgence of the king, it was allowed for above a century to omit making returns; but from the 26th Henry VI. (1447) it has regularly returned two members. Edward IV. granted the boroughs of Burgess Hill and Royston.

The limits of the municipal and parliamentary boroughs are identical, and comprise the whole of the parish of New Windsor, with the exception of the small hamlet of Dedworth, which is separated from the town by an intervening parochial district. A part of the parish of Eton, to which the town of Windsor has extended, is comprised within the borough; and on the passing of the Reform Act an extra-parochial division, called the Lower Ward of the Castle, containing the residences of the Duke of York and the Duke of Devonshire, was incorporated.

Windsor was made part of the borough. Though situated on opposite banks of the Thames, Windsor and Eton form in appearance but one town, the line of houses being interrupted only by the bridges. Eton was erected in 1524, 200 feet long and 26 wide, and consisting of three arches. Windsor is pleasantly situated on rising ground, and consists of six principal streets, well paved, and lighted with gas, besides a number of smaller streets of rather mean appearance. The watch is very defective. The population of the parish, in 1841, was 7528, including 101 in the hamlet of Dedworth. The borough contained 1072 inhabited houses, and the population was 7786, but this included 789 males and 124 females in the infantry barrack, soldiers on guard, 11 persons in the gaol, and 150 strangers. The number of persons in the Castle (Windsor Castle, Upper Ward, extra-parochial) was 30 males and 56 females; in Windsor Castle, Lower Ward, and extra-parochial, 1244 males including 44 persons in barracks at the Hospital. The number returned in the borough as born in the county was 3076, and elsewhere 4710, including 512 born in Scotland and 900 in Ireland.

Prior to the passing of the Municipal Reform Act in 1835, the corporation was governed by a charter granted in 16 Charles II., under which it consisted of the mayor and nine other chief burgesses, or aldermen, three bachelors, and fifteen or seventeen younger brethren, who were elected by the higher class in the city, and re-elected, there are six aldermen, one of whom acts as mayor, and eighteen councillors. The borough is divided into two wards, and the number of burgesses on the borough register was 569 in 1836, and 616 in 1837. There is a separate commission of the peace for the borough, and offfenders are committed to the borough gaol. In 1840-41 the ordinary municipal expenses were—police and constables, 660l.; administration of...
justice, 1704; gaol, maintenance of prisoners, &c. 100l.; allowances to municipal officers, 37l. 4d. In the same year the receipts under the head of rents, fines, or licenses, was 542l.; tolls and dues, 20l. 1l.; borough and gaol rates, 67l.; miscellaneous, 24l. 1l.: making, with other items, a total of rather less than 1,000l. The corporation assurred the exclusive right of voting in the election of members of parliament, but it was afterwards extended to all the inhabitants paying scot and lot. The greatest number of electors polled at any election during the next hundred years before the passing of the Reform Act was 363: in 1830-40 the number of parliamentary electors for the borough was 667.

The public buildings of Windsor (exclusive of those pertaining to the Castle) are not in any way remarkable. A notable exception is the Hall, which will be found in the next chapter. [WINDSOR CASTLE.] The Lower Castle Ward is divided into two parts by the Collegiate Chapel of St. George, which stands in the centre. A chapel dedicated to St. George, for the service of the Order of the Garter, was erected at Windsor by Edward III. (1327-77); but the present edifice was begun by Edward IV. (1461-83), and was not completed until after the commencement of the sixteenth century. It is one of the most beautiful specimens of ornamental pointed architecture in this country. The noble proportions of the interior, the richly-carpeted roof, the painted windows, the banners and escutcheons of the Knights of the Garter overlooking their carved stalls, within which are fixed the armorial bearings of these illustrious Commanders, are all from the times of its founder, Edward III., alike impress the mind with a sense of beauty and powerfully seize upon the imagination. The great east window is painted after the designs of West; and over the altar is one of West's best productions. The Lady Chapel of St. George (in which the last Princess Charlotte is interred) in St. George's Chapel. Edward IV. is buried here, beneath the steel tomb executed by Quintin Mates. Henry VI. lies under a plain marble in the opposite aisle. Henry VIII. and Charles I. are entombed under a common tomb. At the south end of this passage communicating with the tomb-house, in which George III., George IV., William IV., and others of the present royal family are interred, St. George's Chapel is a collegiate establishment. The chapter consists of a dean, eight canons, and six minor canons; and its gross annual revenue, for the three years ending 1831, averaged 22,475l., net income 19,380/. The old church was pulled down in 1818, and the present edifice was completed, in 1822, in the latest pointed style. The building is a specimen of ecclesiastical architecture, with the gift of the crown, valued at 400l. a year. That are places of worship for several denominations of Dissenters. The guildhall or townhouse, erected in 1688, is rather a handsome building, supported by pillars and arches of Portland stone. There is a number of portraits of the English and personages of rank in the hall or courtroom; and externally, at each end, there is a statue of Queen Anne and one of her consort Prince George of Denmark. A free-school was erected in 1706, and is partly supported by endowments. The charitable institutions comprise Brotherton's hospital, founded in 1503, for eight poor persons; Reeves's almshouses, founded in 1676; besides a dispensary, lying-in hospital, &c. There are barracks for infantry and cavalry, the latter in Clewer park. The little town of Eton is placed near the river and is situated in the midst of the village. The Castle is surrounded on two sides by the Little Park, a very antient and beautiful domain, which at one time formed part of Windsor Forest. Within its precincts is Eton College Lodge, now occupied by the Duchess of Kent: the grounds comprise 600 acres, and a rich park is laid out with great taste. In the reign of Queen Anne that part of Windsor Forest which remained the property of the crown, under the name of the Great Park, was ceded to the Earl of Pembroke, and the Castle by the private proceeding of the same queen, and it was therefore determined to buy as much land as might be required to complete an avenue from the Castle to the forest. This is the present Long Walk, generally considered the finest thing of the kind in Europe. It is a perfectly straight line, above three miles in length, running from the principal entrance to the Castle to the top of a commanding hill in the Great Park called Snow Hill. On each side of the road, which is slightly raised, there is a double row of stately elms, now in their maturity. The view from Snow Hill is very fine. In 1632 a colossal equestrian statue of George III. was erected on the highest part of this hill. The total elevation of the statue and pedestal exceeds 50 feet, and the statue (man and horse) is 26 feet in height. The walks and drives in the Great Park present scenes of great beauty and variety. At the southern extremity of the old park, where the river Thames is longest in length, forming the north side of the great quadrangle. Fortunately this has been preserved, owing perhaps partly to its situation, for, although a mere 'bit', it is a singularly fine one, and a noble specimen of palatial architecture in that particular style.
During the three following reigns no additions were made. The reign of Elizabeth, on the contrary, forms almost an epoch in the architectural history of the Castle, because, though she did not domineer in it, in the way of building, except annexing to the portion added by Henry VI, that which is distinguished by the name of Queen Elizabeth's Gallery, she first caused the terraces to be formed, thereby giving to the royal abode of Windsor what is not the least striking or least attractive of its characteristics. Under the Stuarts no work was done until the Restoration; when the Castle began to be modernized, and in such a tasteful and insipid manner as to have no quality of style of any kind, and no grandeur but what was derived from mere size. The principal addition made by Charles II. was the St. George's Building (containing the State apartments, shown to the public); and no doubt this was a very great improvement as regarded the accommodation required for courtly parade. The rooms were sufficiently spacious and lofty, with large arched windows, commanding an enchanting prospect; but in themselves they had little of architectural character and embellishment, except what they derived from the pencil of Verrio. In saying this, we are aware that we have what may seem very strong authority against us, a very different opinion being expressed by the author of the interesting and valuable description which accompanies the Illustrations of Windsor Castle, edited by H. Ashton, Esq. After observing of the rooms generally that they were 'in a style of architecture which may amuse, and doubtless succeed in what is called its want of purity,' he adds, 'the ceilings especially were decorated in the noblest style at has ever been devised.' Without reference however to execution and the degree of talent, or the want of it, so manifested, we maintain that every line of the whole building and decoration is decidedly unarchitectural in its effect. What precise share Sir C. Wren had in the improvements of this period is not stated; but where further additions were afterwards completed by William III., he recommended that all the buildings on the south side of the Upper Ward, as far as midway of the Keep, should be replaced by an entirely new and uniform range to be erected, forming a regular ensemble externally composed of a projecting centre and wings. This scheme however was dropped; nor is it perhaps to be regretted, as it would have added Hampton Court, or else what was then done might have stood greatly in the way of further improvement.

The first two Georges did nothing for Windsor; George III., on the contrary, much, if only by restoring the interior of St. George's Chapel (1787-90), which, little as the execution of Gothic was then understood, was done in so judicious a manner, by scrupulously following the original details, that it requires no experience to detect inaccuracies. Sad mischief however was done by removing the mullions and tracery of the east window and those at the west end of the aisles, in order to fill them up with plates of glass, after designs by West. In 1790 James Wyatt was first employed at Windsor, and Gothicised the Star Building and the corresponding portion on the north side of the inner quadrangle as far as St. George's Hall. He also fitted up the state staircase in the same style, and did something to better the domestic arrangements of the interior; but the improvement, such as it had been, stopped, while what had been done produced little other effect than that of making the rest of the Upper Ward and buildings towards the terraces appear meaner than before. Still it was fortunate that the works were interrupted, for had they been carried on till the whole exterior of the presence portion of the Castle had been completed in the same style and on the same scale as then begun, Windsor Castle would have been greatly inferior to what it is now.

Excluding beauty of situation, the Castle had nothing whatever to recommend it as a residence. The whole of the east and south sides, the portion being immediately in view from the new place, was singularly inconvenient in every respect, and also exceedingly confined in its accommodation. The rooms, and those for the most part of the courtiers being no other communication got out from them on the sides that point of communication (which is what the Frenchmen always call the 'troue') to the battlements.
delicious wine, has scarcely a quality, except durability, like that of the original.

Some local produce effects which are alike inexplicable and inimitable. These, though generally attributed to the soil, are not always or solely owing to its composition and qualities. In some instances the soil is the main cause of difference, as seen in the Constancia of the Cape. The climate there is most favourable to the growth of the vine, yet in one small space only is a tolerable wine produced, the two contiguous farms of the Great and Little Constancia, yielding, the former the red sweet wine, the latter the white Constancia; the soil on which the vine is decomposed and grown: Whereas the precipitate difference of soil can be point out, differences arise from the cultivation of a different kind of grape. Under the article Vins (vol. xxvi, p. 398) it is stated, on the authority of Meyen (Pflanzen-Geographie, p. 432) that there are instances of the same variety of wine being planted on the side of a hill or mountain, and the wine which is the produce of the grapes from the highest part of the mountain will differ essentially from the wine which is the produce of the same grape from the lower part of the mountain. The wines known by the name of Johannisberger and Rudesheimer in Germany are the produce of vines growing close together, and resembling each other in external characters. The vineyards also that produce the Loheberger and the Sud are very similar to each other. It is probable that this difference is owing to the composition of the soil. This is not altogether correct. Johannisberger is only 150 feet above the level of the Rhine, and it is quite certain that the produce of the vineyard at Leistenwein, which is near the city of Johannisberg, of a quality vastly superior to the produce of the place called Johannisbergerhöhl, not from any peculiar or insurmountable cause, but because the former, belonging to Prince Melchers, and the latter to some other proprietor, can receive an amount of skilful treatment, which the other, being divided among a large number of small proprietors, never does. This subdivision is the cause of an annual loss of many thousands of pounds. (Bronner, Die Wein- und Tafeltrauben der Deutschen Weinberge und Gärten, Heft v., t. 46, p. 113.)

The grape cultivated in both places is the little Riesling (Der Kleine riesling of some, Weisser riesling of others; the Vitus vinifera purilla of Babo and Metzger's Wein und Tafeltrauben, p. 159). It can be grown to ten feet high (which occupied ten years in building). This greatly promotes the steady progress to maturity of the grapes by securing a quissent state of the air, which is known to be extremely beneficial, and which, when imitated, produces a rich, fragrant, and agreeable vintage. The bunch of grapes with a muslin bag, forwards its ripening very much. The wine of Lugisland and the Liebfrauenmich owe their superiority over that of the neighbouring vineyards to the protection of the town-wall of Worms. (Bronner, Heft ii., pp. 18-20.)

The advantage of protection against agitation of the air is so well understood in the Rheingau, that the belts of vineyards which clothe the height of Hochheim bring very different wines, according to the direction of the wine. One morgen to the right of the river Main, brings in the market two thousand florins; a higher morgen brings one thousand florins; and one at the summit only five hundred. (Bronner, pp. 14.) The geographic character of the soil of Johannisberger is argilaceous, which is known to be of peculiary much benefit to the grape, and in one place passes into a reddish quartz, which is very hard, and stands but slowly any decomposition. This is overlaid with alluvial and alluvial deposits in most places, in south-west side from these and circumstance it follows that the soil is of a very diversified character. (Bronner, p. 116.)

The exposure is south-west, with a slope of from ten to fifteen degrees. Rudesheim is well protected by its natural position and a lofty fortification, so that it is almost impossible to be kept from being washed down only by numerous terraces, between which the air is as hot as in a conservatory. The soil is composed of stones of a dark colour, which radiate heat during the night to such a degree, that the grapes are surrounded by almost the southern climate. The grape most common, at least in the old vineyards, is the Rieseling; in the new, new vineyards of the upper Main (U.M., Heft x., t. 60), which has the property, in this story, not ground, of continuing productive till the age of fifty or more, which is not the case with any other grape. But as it only gives a good wine in very favourable years, and as the wine from the Rieseling grape brings so high a price, the new vineyards are mostly planted with the Rieseling; the propriety of this substitution is very doubtful. (Bronner, iii. 130.) These facts are sufficient to account for the differences between the Johannisberger and Rudesheimer wines.

The differences between Leistenwein and Steinwein are still more easily accounted for. The Leiste is on the right side of the Rhine Main, the Stein on the right, the Stein being the most and a large part of it is argilaceous and calcareous portions, especially fragmentary; while this is the soil commonly met with in Wittelsheim and is all Franconia. Why these two wines should differ from all others of the district is unintelligible; but the difference between the Leistenwein and the Steinwein is great. The vineyards of the Leiste (i.e. the best portion, gute Leiste) are planted in a great measure with the Rieseling and Traminer (V. v. tyroliens, B. u. M., Heft xii., t. 72,) with about a third of the Elbling grape (V. v. albula, B. u. M., Heft x., t. 72). The Steinwein is equally divided between the Traminer, called franken, by some geweldel (V. v. u. m., B. u. M., Heft ii., t. 9), i.e. both white and black. Besides these there occurs in considerable proportion the Hermitage grape, brought from France, which here succeeds to the Rieseling. This soil, regarded as calcareous, granite, the selection of the grapes, when ripe, is attended to with extraordinary care. (Bronner, vi., p. 82.)

The predominant grape of the Stein vineyard is the Elbling, mixed with a smaller proportion of the Rieseling and Hamburg grape. The Leistenwein is with justice regarded as the second finest wine of the south of Germany, but as the whole of the produce of the small space known as the gute Leiste (containing only 2 morgens towards the south-east and 2 morgens towards the north) is the wine of the Stein, it is commonly sold as a wine of Bavaria, it is scarcely known, and is seldom to be purchased. The Steinwein must not be confounded with the Steinberger wine of the Rhine.

The Montilla of Spain is the produce of a white soil (called calcarous, containing a great part of carbonate of lime, with aluminia, silica, and a little magnesia), while the Manzarella is the produce of the terrains rouges et ablo- nœux. Yet the wines do not greatly differ in taste or flavour. More importance is attached to the soil than the grape; but the climate, if anything, is better than its chemical; Chaptal was clearly of this opinion, for he maintains that, provided it is porous, free, and light, its component parts are of little consequence. Perhaps calcarous is on the whole the best, simply because it yields slightly better grape than the others. In the south of Spain, the air and climate are much more susceptible to the influence of the soil being the cause. 'In all those districts which produce wines of high reputation, some few individuals have seen the advantage of selecting a particular variety of grape, and the climate be so advantageous that the highest state of perfection of which it is capable. The same care has been extended to the making and subsequent management of their wine, by seizing the most favourable moment for the vintage—by the rapidity with which the wine is made; the climate and soil are such that the whole content of each vat may be in exactly the same state, and a simultaneous and equal fermentation be secured throughout—by exercising equal discrimination and care to those that bring off the vintage. And in its consequent treatment of wines where it is kept; and lastly, by not selling the wine till it should have acquired all the perfection which it could acquire from age, and by keeping, as the produce of their own vineyards, such wines, to confirm and maintain its celebrity. By these means have the vineyards of a few individuals acquired a reputation which has enabled the proprietors to command almost their own prices for their wines; and it was evidently the interest of
such persons that the excellence of their wines should be
imputed to a peculiarly in the soil, rather than to a system
of management which others might imitate (p. 139).

It is greatly to be wished that the truth of this
important statement were impressed on all persons having
the character of vine-growers, as it is certain by attention
to these and other circumstances quite within their control,
the quantity of good wine might be much increased and
its price lessened. Bronner distinctly states that in the
Bergstrasse near Heidelberg, by obstinate adherence to
careful and judicious practice, the produce is annually one-
third less than it might be (beh vii., p. 20).

Where some peculiar strong-smelling substance exists in
the soil, an odour is communicated to the wine which ren-
ders it unpleasant. This is the case when stinkweed (a
native of United States) is present. (p. 44) not only with fresh cow-dung, which is used at
Johannisberg, but with fragments of woolen cloth previously steeped in liquid manure and dried, which is
found greatly to augment the produce. Professor Rau
believes a vegetable cause to be the utility. The practical
value of the addition of old lees to the red than white grapes; the former every
third or fourth year, the latter only every tenth. Even
the proprietors of the vineyards near Bordeaux, which
produce the highly-prized clarets, employ manure once
or twice a year. (Paguier, Wine, 4th ed., p. 28.) But perhaps the best manure for vines is the cut-
tings of the vines themselves when pruned, as recom-
mended in Liebig's 'Chemistry in its application to Agri-
culture,' 2nd edit, p. 290.—The vines are pruned in the end
of July or beginning of August, whilst still fresh and
moist. If they are then cut into small pieces and mixed
with the earth, they undergo putrefaction so completely,
that at the end of four weeks not the smallest trace of
them can be found. These restore to the soil the alkalies
absorbed by the grapes, which are so necessary for the per-
fection of this fruit. Probably no farm, so rich in alkalies,
would answer well. But the same vines will yield a wine
having very different qualities, at least as to flavour and
perfume, in different seasons. These qualities are, in
truth, of such a variable nature, that they might be said to vary from year to year; there being perhaps no
two vintages, though collected from the same spot and
managed in the same manner, that will be found com-
pletely different in color and perfume. (History of Antient and Modern Wines, p. 135.) The cor-
rectness of this statement is proved by the varying charac-
ter of the vintages in different years, as seen in the fol-
lowing table, in which it may be observed that the season
which was favourable in the vineyard in one place, was fre-
guently unfavourable to it in another. Hence it rarely
happens that the good Port years coincide with the good
Claret years, as a heat which ripens well the grapes in the
comparatively cold climate of Medoc searches the grapes in
the warmer climate of the Douro. The close mutual rela-
tion, so often called the comet year, was remarkable for the ex-
cellence of the vintage in almost all the wine-yielding
countries of Europe.

The mode of planting, pruning, training, pruning, and
renewing the vines has a very great influence on the quan-
tity and quality of the produce. At the present time,
grow unrestrained is a sure method of deteriorating the
quality; and although the picturesque appearance of
the vines spreading in graceful festoons, a sight only to be
seen in Italy and a very few places in the south of France,
corresponds to the idea formed of a vineyard, yet all skilful
cultivators keep them low. This method is followed in
France, Germany, and Portugal; in the very sandy parts
of Spain; they are even allowed to trail along the ground.

Elsewhere they are supported by props or trellises. The nearer to the ground the grapes are kept, the more potent is the wine; moreover the vines flower earlier and the grapes are sooner ripe, thus rendering the vintage more certain. Along the Moselle, at least in the old vineyards, where the vines are allowed to grow six or nine feet high, the wine of these vineyards is much lighter than that of the same or similar vineyard on the Moselle. At Orval, on the other hand, a very peculiar mode of training the vines is followed; and the vine there is also very light, destitute of the fiery character of those of the neighbourhood, and, being less esteemed, sells for one-half less; it is however a very wholesome wine.

If the soil be stony and of a black colour, there is great advantage in having the grapes near it, as they not only get the benefit of the reflected light during the day, which, coming on the lower and under parts of the branches, colours the fruits, and paragelie, against hail. Numerous insects infest the vine, some of which are very destructive. (See a very complete account of them by Baron Walckenenaer, in Taylor's Scientific Memoirs, vol. i.; and in the work of Költer; also Victor Audouin, Histoire des Insetes nuisans, et perturbateurs de la Pyramide, 1842.) The crop is also apt to be ruined by excessive wet, either early in spring or when the grapes are approaching maturity; the rains which fell in September, 1842, completely ruined the claret vintage of that year, which was in the process of ripening. The360 do not change for many days before the white. It is of importance to use one kind only, or, where several are used, to be careful that they reach maturity at the same time. Upon the careful selection of the grapes when in perfection depends much of the superiority of the Johannisberger and other of the most famous Rhine wines, three successive gatherings being often made, at considerable intervals. The removal of every unripe grape from each bunch is also carefully performed in the well-ordered vineyards. The stage at which the grape is fit for gathering varies. The nature of the kind of wine intended to be made. When a brisk wine is wished, such as Champagne, the grapes are gathered before they are fully ripe; and they may be collected even in foggy weather. If the dew is drained from the vines, though for all other kinds dry clear weather is proper. (Henderson, p. 15.) This author (in general so accurate) states that if the object be to obtain a dry full-flavoured wine, the grapes should be gathered as soon as they have acquired their proper maturity, and before they begin to shrivel or wither on the stalk. But in the case of the most esteemed German wines, which are the driest of all, the gathering of the grape is postponed as late as possible, by which many free acids are got rid of, and the wine at such a period of keeping is so soft and delicate, that the new wines are preferred to the extremely old wines, which were in great request previous to the adoption of the plan of late-gathering. Thus at Johannisburg the vintage of 1831 was very late; that of 1831 did not come on the market till the 17th of November; and in 1834 the grapes were all hanging on the vines, but perfectly sound, so late as November. Yet these are among the most renowned vintages of the present century.

In the warmer parts of the south of Spain and of France, and also at Tokay, where wines de liqueurs are made, the grapes are allowed to remain very long on the vines; the stalks are twisted, so as to prevent the influx of any recent sap; the thinner or watery portion evaporates, and the dry or shrivelled grape remains, and contains much sugar. On the Rhône a small quantity of sweet wine is made from the ripest grapes, which are hung on hurdles, or spread on straw, for six or eight weeks, or until they become half dried. The liquor obtained from them, which is called le vin de paillasse, is a straw wine (vin de paillasse). In some cases the mas is boiled; this is often done with the sheries of Spain. When the boiling is carried far, a very sweet luscious wine is produced, such as the wine of Cyprus, the malmsey of the Italians (vinum coctum of the ancients), the malmsey of Cephaloia, and the other rich wines of the Greek Archipelago.

The process pursued with other wines, though subject to modifications in the different kinds, is perhaps the best learnt from the practice pursued in the Claret country. It is universally allowed that the highest degree of skill, attention and experience is exhibited. But before giving the details it is necessary to take a view of the chemical composition of the grape and of its juice, both in the unripe and ripe states.

The grape itself has not been made the subject of rigid chemical analysis, but the juice (called verjus) of the unripe grape, and that of the ripe (termed must), has been analyzed by the following chemists:

Béard also found an odorous matter (to be afterwards spoken of), also malate of lime and super-sapum of lime.

The seeds of the grape yield the purest tannin; fixed oil exists also in the seeds and kernels of the grape, and is especially abundant in the south of France. The colouring principle resides entirely in the skin, hence the wine in the grape called Tintillas (from which the wine called tintilla of Spain is made), and which is entirely penetrated by the colouring principle. It is used in dyeing, hence called by the French leint’sur, or l’Alicant.

The juice of the grape is a subject of investigation on the colour of the grape from which it is prepared. Champagne is the produce of a red grape: red and white grapes are used indiscriminately for Sherry; but white Port is made only from a white grape.

The stalks promote the fermentation, and if they, as well as the hulls or skins, are withdrawn before the fermentation has proceeded far, it is not till some alcohol is generated that the colouring principle is dissolved, these two red grapes neither communicate colour to the wine. They are early wines from the delicate red wines of Bordeaux; but retained longer in the red wines of Portugal; hence the greater austerity and sponginess of the latter. The wine of Cahors, prepared from a grape called Auxerrois, pied de gueule, yields a wine a dead black, the colour being deepened by an admixture of a preparation called vinigone, which is merely a portion
the must of this grape, boiled for a few minutes with the strongest spirit of wine, in the proportion of one part of spirit to four of must, added to it. This extracts the colouring principle most thoroughly; and communicates not only the colour, but all the rest of the bouquet, of the Bordeaux wines, to which raugme is frequently added, a deep hue. 'The more this preparation is required and added, the less the wine will bear keeping.' (Paugerolle, p. 112.)

The wines of the Moselle may be distinguished from those of the Rhine by their being put in curvés-mères or mother-casks, to which a yellowish colour is given. At Conin, in Moldavia, a wine is prepared which is green, and which becomes deeper by time, while the strength increases so much, that it is not kept any longer in a cask. In the third or four years it almost resembles brandy, but without so readily affecting the head. 'On exposing red wines in bottles to the action of the sun's rays the colouring-matter is separated in large flakes, without altering the flavour of the wine, and the wine becomes white, or a pale straw colour, which, after three or four years it almost resembles brandy, but without so readily affecting the head. On exposing red wines in bottles to the action of the sun's rays the colouring-matter is separated in large flakes, without altering the flavour of the wine, and the wine becomes white, or a pale straw colour, which, after three or four years it almost resembles brandy, but without so readily affecting the head. The wine, if it has succeeded, ought to be clear, transparent, of a fine soft colour, a lively smell, and a balsamic taste, slightly piquant, but agreeable, inclining to that of the raspberry, violet, or mignonette, filling the mouth, and passing without irritating the throat, giving a gentle heat to the body, and not causing the lower parts of the body to be heated.

It is necessary to know what is meant by the 'flavour' of wine, and what is meant by 'bouquet,' terms often confounded. The flavour of wine, called by the French sève, indicates the vinous power and aromatic savour which are felt to the air of the wine without entering the mouth, and continuing to be felt after the passage of the liquor. It seems to consist of the impression made by the alcohol and the aromatic particles which are liberated and volatilized as soon as the wine receives the warmth of the mouth, or as soon as it is tasted, or even as it is splashed on the palate, inasmuch as the latter declares itself the moment the wine is exposed to the air; it is no criterion of the vinous force or quantity of alcohol present (being in fact greatest in the weak wines), and influences the organ of smell rather than that of taste. The bouquet which by these means is given to the common or ordinary wines never replaces perfectly the natural flavour of the choice wines of Medoc and Graves. It is very easy to distinguish the bouquet from the bouquet by even moderate experience in tasting wine.

The bouquet of wine is altogether a new product, and is in no way dependent on the perfume of the grape from which the wine is made. Red wines scarcely ever retain a trace of the bouquet. (See p. 30.) In the white muscadine wines do in some degree, especially Frontignan. It has been recommended to suspend some of the ripest and most odoriferous bunches of the grapes in the cask after the first fermentation has subsided, in order to heighten the perfume. A practice long pursued in the vineyards of the Italians, and wines of the French. But if the acetic acid and amanitic acid, upon which the bouquet depends, be the consequence of a true process or putrefaction (somewhat similar to what occurs in musk, by which the scent is evolved), by the action of the elements of oxygen and sugar, this process cannot accomplish the object, and only runs the risk of exciting a hurtful fermentation. The best account of the bouquet of wine is given by Liebig, who, with Pétouze, discovered amanitic acid. It is well known that those wines and fermented liquors generally contain, in addition to alcohol, other substances which could not be detected before their fermentation, and which must have been formed, therefore, during that process. The smell and taste which distinguish wines of different periods of fermentation is similar to the smell upon an ether of a volatile and highly combustible acid, which is of an oily nature, and to which the name of amanitic acid has been given. Amanitic acid contains an equal number of equivalents of carbon and hydrogen—exactly the same proportions of these elements, therefore, as sugar; but by no means the same proportion of oxygen.

The substances in wine to which its taste and smell are owing, are generated during the fermentation of the juice of the grapes as contain a certain quantity of acetic acid; they are found in wines which are free from all acids, or which contain a different organic acid, such as acetic acid.

The wines of warm climates possess no odour; wines grown in France have it in a marked degree, but in those from the Rhine the perfume is not pronounced. The kinds of grapes on the Rhine which ripen very late, and scarcely ever completely, such as the Rieseling and Orleuran, have the strongest perfume or bouquet, and contain proportionally a larger quantity of tartaric acid. The earlier grapes, such as the Ruländer and others, contain a large proportion of alcohol, and are similar to Spanish wines in their flavour, but they possess no bouquet.

The grapes grown at the Cape from Rieslings transplanted from the Rhine, which ripen quickly into the ripened wine, which does not however possess the aroma which distinguishes Rhenish wine. It is evident from these facts, that the acid of wines, and their characteristic perfumes, have some connection, for they are always found together, and it seems to be essential that the composition of the wine should give a certain influence on the formation of the latter. Whatever opinion may be held regarding the origin of the volatile odoriferous substances obtained in the fermentation of wine, it is quite certain that the characteristic smell of wine is owing to the ripening, or a bouquet of an organic acid, resembling one of the fatty acids.

It is only in liquids which contain other very volatile acids, that the fatty acids and amanitic acid are capable of entering into combination with the other of alcohol, and thus producing two kinds of aromatic matter, which is found in all wines which contain a free acid, and is absent from those in which no acids are present. The acid, therefore, is the means by which the smell is produced; a small without its presence amanitic acid could not be formed.

On the Rhine also an artificial bouquet is often given to wine for fraudulent purposes, by the addition of several species of the sage and rue to the fermenting liquid; but the perfumes thus obtained differs from the genuine, and is known by its inferior durability; they are gradually dispersed. (Liebig's Organic Chemistry in its application to Agriculture, 2nd ed., p. 313.)

The fermentation is more prompt and lively in proportion to the quantity of must; hence the best wine is made when a large quantity of must is operated on, it is only when a very small quantity of some peculiar grape is to be fermented that small vats are ever used. In some cases, when the season is cold and the grapes are very tender, it is necessary to ripen the wine by artificial means; either adding some boiling must, or withdrawing some of the excessive water by adding baked gypsum. This last uneconomical proceeding is now laid aside in France, being succeeded by the practice that was pursued in the Rhine, where a little must is first carried on in covered vats, since in open ones only the carbonic acid escapes, by which the wine is rendered flatter, but much of the alcohol and aroma are lost, and the wine rendered weak. The length of time that the fermentation continues is the chief characteristic of the kind of wine intended to be made. The temperature influences its progress and the results. In the Champagne country, the grapes which are to fill one cask are all pressed within the space of two hours, and the must allowed to ferment in small vats, from six or twelve to eighteen hours, according to the temperature, during which it undergoes a process of spontaneous purification, becoming as clear as water. The moment when this is complete is watched for with the utmost care, as it is then drawn off into small vats, completely well sulphured (a process which is hereafter explained), and put into cellars below ground, the bunghole being left open but covered with a fine stone. The overflowing fresh, or yeast, is removed from time to time till December, when it is necessary that the wine be tasted and proved. It is then also submitted to the process of fining.

At Tokay the must is allowed to remain in the vat from twenty-four to thirty-six hours, till the first or spontaneous fermentation are made, and the wine is then divided off into small casks (which are never sulphured) and placed in a still part of the cellar. The effervescence lasts two or three months.

The fermentation spoken of hitherto is called the primary or active fermentation; but there is another kind, called the seconde or induced, which, though obviously a continuation of the former, is less attended to, but yet of great importance as relates to the ripening, keeping, and acidity of the wine. A knowledge of the cause of fermentation, and the different conditions under which it can take place, is most material to a full comprehension of the measures necessary for ripening the wine and preserving it in perfection. The subject has been fully explained in Liebig’s Chemistry of Agriculture, and a summary only can be
given here. The cause may be expressed in the following law of La Place and Berthollet:—"A molecule set in motion by any power can impart its own motion to another molecule with which it may be in contact." Fermented yeast is a body in a state of decomposition, the atoms of which consequently are in a state of motion or transposition. Yeast placed in contact with sugar communicates to the elements of that compound the same state of motion; but it does not contain enough of the sugar to arrange themselves into new and simpler forms, namely, into alcohol and carbonic acid. In these new compounds the elements are united together by stronger affinities than they were in the sugar, and therefore under the circumstances in which they were produced further decomposition is arrested.

In the juice of the grape fermentation is excited by the access of air, alcohol and carbonic acid being formed by the combination of these three things, or sweet wines. But when the process once commenced, continues till all the sugar is completely decomposed, quite independently of any further influence of the air. In addition to the alcohol and carbonic acid formed by the fermentation of the juice, there is also produced a yellow or grey insoluble substance, containing a large quantity of nitrogen. It is this body which possesses the power of inducing fermentation in a new solution of sugar, and which has in consequence received the name of ferment. The alcohol and carbonic acid are formed from the prototypical quantity of ferment from those azotized constituents of the grape-juice which have been termed gluten or vegetable albumen. Gluten dissolved in pure water undergoes a process of decomposition; but the decomposition which it suffers in an insoluble precipitate of gluten. The gluten, when introduced into a fresh solution of sugar, and retained in a vegetable juice, belong to two different kinds of transformations. There is reason to believe that its change to the insoluble state depends on an absorption of oxygen, for its separation in this state may be effected under certain conditions by the introduction of nitrogen. Different specific effects seem to be present in different fermenting fluids; hence the names S. vini, cerevisiae, and pomorum, according as it exists in wine, beer, or cider. (Schwann, P. Liebig's Vol. cxxiii. 1838, p. 66; Meyen, Report on the Progress of Vegetable Physiology during the Year 1857, p. 83; Meyen, Jahresbericht von dem Jahre 1856, p. 56; Meyen, Quaestiones, mer. 1858, f. 22; Quevénne, Journ. de Pharmacie, Juni, 1836, p. 259; and British and Foreign Med. Review, vol. ix., p. 579.)

Quevénne has found that, though the development of the fungus and fermentation are two distinct operations, whatever represents the growth of the former hinders the latter. Certain free organic acids must be present, and alkalis, which combine with them, stop completely the process of fermentation.

The knowledge of these facts will enable us to comprehend the nature and object of the practices adopted empirically for the preservation of wine; above all, of those which are requisite to prevent it passing into the state of acetic acid, to which the wines of northern countries, or poor weak wines, are most prone.

The whole process may be simply expressed thus. Grape-sugar is a compound of carbon, hydrogen, and oxygen. In the action of fermentation the relative proportion of the atoms is disturbed, owing to the presence of an ex-cit-er (ferment), by which certain new compounds are produced (the former in a great measure flying off in the form of gas), the result being a diminution of the atoms of carbon and oxygen:

Three atoms of sugar = 3 atoms hydrogen, 3 atoms carbon, 3 atoms oxygen, decomposed;
One atom of alcohol = 3 atoms hydrogen, 2 atoms carbon, 1 atom oxygen, formed.
One atom of carbonate of sodium = 1 atom carbon, 2 atoms oxygen, formed. (Acocol.)
So long as any sugar is present, the power of the gluten (exciter) is exercised in converting it into alcohol; but no sugar remaining, its energy is directed to the alcohol, which is changed into vinegar by acquiring one atom of oxygen; yet not immediately, as is frequently stated, but through the influence of aldehydes, which is alcohol deprived of two atoms of hydrogen, the hydrogen being oxidized into water.
dised at the expense of the oxygen in contact with it, and the same is true of the aldehyde, having a great affinity for oxygen, combines therefore directly with it, producing acetic acid. The formula for these is as follows:

Grape-sugar . . . C12 H14 O14

This contains exactly the elements of four atoms of acetic acid gas and two atoms of alcohol.

The formation of acetic acid from alcohol consists of two stages: 1st, the abstraction of hydrogen, by which aldehyde is formed; and, 2dly, the addition of oxygen, by which acetic acid is produced. Alcohol gives by reaction:

\[ \text{Aldehyde} \text{C4 H4 O2} \]

and this gives by:

\[ \text{C4 H4 O2} + O \]

Hydrated acetic acid.

\[ \text{C4 H4 O4} \]

Or hypothetical dry acetic acid

\[ \text{C4 H4 O3} \]

(Kane's Elements of Chemistry, p. 896, etc.)

The one atom of hydrogen taken from the aldehyde has combined with one atom of oxygen to form water, which also results from the process. Hence the necessity of excluding the atmospheric air, as the chief source of oxygen; or introducing some other element with which the oxygen more readily than the aldehyde can do; or keeping the alcohol at a low temperature, which is adverse to this combination. These various objects are attempted to be accomplished by racking, sulphuring, fining, racking, bottling, and keeping the wine in casks at the temperature of the air.

It must be obvious that the employment of these means is directed against the occurrence of the acetic fermentation, which mostly happens to cause the spoilage of the wine, and altogether unnecessary, since, so long as the vinous fermentation is going on, i.e., as long as alcohol continues to be generated, the wine is gaining in quality. Once begun, the presence of atmospheric air is nowise necessary for the continuation of the vinous fermentation; the more thoroughly it is excluded therefore, while the vinous (insensible) fermentation, by which the wine is ameliorated, goes on, the acetic fermentation cannot commence.

This probable extract from Liebig, it appears, that while the azotised matter (gluten) in grapes, wherever grown, is a fixed quantity, the acids and saccharine matter are variable. When there is more saccharine matter, as in Rivesaltes, Frontignan, and Tokay, than is introduced into the juice to transform into alcohol, a portion of the undecomposed sugar remains, sufficient not only to give that taste which has acquired for them the name of sweet wines, but also to exert the usual preservative power of sugar, when present in large quantities, and resist decomposition. Thus Muscadine wine has been kept two hundred years; Mountain, buried at the time of the fire of London, and disinterred in 1811, was excellent; and old Tokay, called vino extrasenso, is in perfection at the end of a century. This wine needs neither sulphuring nor adding to it, as fine Scharlau, Ungarn Weinbrand, eerst band, p. 79: the casks are hermetically bunged. And the reason is obvious. To the juice of grapes grown in colder climates or cold seasons, sugar, especially starch-sugar, is added at the beginning of the fermentation, in order to consume and the leaven. Also to wine which it is apprehended is about to become sour, or pricked, as the first sign of its becoming acetic is termed, sugar is also added; but if vinegar has really been formed, this introduction of sugar, so far from hindering, only hastens the further transformation, as the presence of vinegar is the most powerfully disposing agent to this.

When a dry wine is wished, it is necessary that all the sugar should be transformed into alcohol. To do this the wine is racked to time, and by rote or racking, or by returning it to the lees to feed. As the wine contains variable quantities of undecomposed gluten in solution or thrown down to the bottom of the cask, it is only necessary to stir up the lees to re-oxidise the fermentation.

But lest the point should be passed when the vinous fermentation is nearly complete, and the acetic would begin, all the undeveloped ferment is removed. Most of it remains in the vat in which the first and final fermentation takes place; while the ferment put in casks, these are generally kept nearly full, by frequent additions of fresh juice, so that much of the ferment works out at the bung-hole, which is seldom perfectly closed for two or three months. Racking is practiced for various wines, as often by three times in the year. This consists in transferring the wine to a fresh cask. It is in doing this that the practice of sulphuring is most adopted. It consists in burning sulphur-matches in a linen steeped in sulphur in the cask, previously rinsed with which all the oxygen of the air is consumed, and a quantity of sulphurous acid produced. This must be carefully done, as, if in excess, the wine acquires the taste of sulphur, which it would keep some time. While wines require most sulphur, especially a pipe of wine, it is principally given immediately to the exhausted cask, otherwise it will speedily get filled again with common atmosphere. Dr. Mc-Culloch recommends the following method, the remarks that by the common method of tapping a scarcity is impossible to draw the sufficient portion of the lees with it:—To effect it, a cock is introduced into the full cask at the usual place of tapping, three or four inches above its bottom, from which a large hose (a flexible esouche) would be introduced into the bottom of the cask. A couple of bellows may then be so fitted to the bung-hole of the full cask as to force by its action the whole of clear liquor through the hose into the empty vessel; this means the least possible disturbance to the wine, as the wine is at the same time preserved from the injurious contact of atmospheric air. (p. 120)

The whole of the wine should not be drawn off, as the cap frequently contains principles which would render it useless for future purposes. A small portion is left in the cask, to form either brandy or vinegar, according to its kind and value. Another means may be used, instead of sulphuring, to prevent the acetic fermentation, viz. the use of potash. A dram of this is sufficient to stop an impatient yeast, and the use of both agents consists in absorbing any trace of oxygen and preventing it acting on the organic substance. Volatile oils have the power of checking the vinous fermentation, but their odour is a practical obstacle to their employment. They probably are the product of the growth of the fungus (Basaccharomyces vinii) formerly spoken of. Alkalies, combining with the free acids, the process of which is essential to the process of fermentation, hinder it, but as they are destructive of the quality of the wine, they are not employed. The use of man- ganase, though recommended by Dr. Mc-Culloch, should never be used for wine where sulphuring has been employed, as it would most readily give off oxygen.

It must be obvious that racking can only bring the wine from matters which are laid bare, and to be either deposited among the lees or floating on the surface. In order to get rid of some other matters held in solution a different practice is adopted. This constitutes the process of fining. It is in all wines of value, and this continued practice is employed for this purpose. The quantity of the wine-finishing is in proportion to the quantity and quality of the wine, as also to that of the material. The common and new wines require more tannin; the old wines require less. The more the fining of the tannin extracted from the seeds of the grape, the glass has no influence in purifying them. If kept in old casks however, as is always the rule in France, they extract tannin from their sides. Numerous processes of improving wines, as well as the permanence of keeping improving wines, are detailed in Jullien, Manuel du Sommelier. The process of fining is always repeated previous to bottling the wine.

At Bordeaux the white wines are generally ready for the first fining or filtering from January to March; the second racking is to prevent the working which the great heat of July and August might occasion in them; and the third in October, before the cold comes on. A favourable state
of the weather must be chosen for these processes; that is, when it is fine and clear, and when the winds are in the north-west, north, or east, because the wine is finer and clearer then than in rainy weather. (Paganiserre, p. 56.)

A Sherry, the unsurpassed produce of one vintage, may now and then, by a rare chance, be obtained. It is difficult to give any rules for the mixing of wines, as the taste and expediency of the maker are the only guides to be depended upon. It generally happens that when two distinct wines are mixed, the process of fermentation is not properly completed, or the process of evaporation, in technical language, is not carried to a proper extent; two casks of very different ages are therefore chosen, in which one or both of the wines to be thus mixed are either in a state of renewed fermentation or show a tendency to it. The wines being then proofed, or as the French term it, the fermentating regenerator, a strong fermentation is excited, which is still further assisted by agitation. When this process, which is conducted with the precautions formerly laid down for the treatment of close fermentation, is completed, the wine is more or less one durable and homogeneous liquid only in consequence of this fermentation. A sense of the quantity of each wine which is to be used, and a proper mixture of the wines, or, if any difference of opinion is to be decided upon, a proof of their sound condition.

A Sherry, the unsurpassed produce of one vintage, may now and then, by a rare chance, be obtained.
Cellars and vaults should be as remote as possible from streets and other ways by which waggon pass, the vibrations caused by these often disturbing the more delicate wines.

When wines have been kept in the wood for the period which experience has fixed as that proper for attaining maturity, they are generally put into bottles or flasks. In these some further change goes on, by which they are still further ameliorated. In many red wines a deposit occurs, forming a crust on the lower side of the bottle.

The operation of bottling should take place in fine weather, if possible in March or April. Before this is done the wine must be fined, either with white of eggs, very fresh, or isinglass; after which the cask must be left to repose ten or fifteen days, according to the weather. The bottles must be perfectly clean, and if not new, care must be taken that no lead-drops remain in them, as these spoil the wine and render it deleterious.

The corks should be perfectly sound, and as elastic as possible, so that when driven home they may expand beyond the contract part of the neck of the bottle, and through those objects which as well as to protect the corks from insects, the mouth of the bottle is often dipped in melted wax. If gum eelli is an ingredient in the wax, insects are less prone to attack the corks. But the wine within often corrodes the cork; this is particularly the case with Madeira and all sweet wines. Such also are most liable to the aggressions of insects, and must frequently be recorked. All these inconveniences, as well as the serious loss of wine resulting from them, are likely to be got entirely rid of by the use of the patent lead-drops stoppers, which besides being in the first instance cheaper than corks, can be often used a second time; they seal hermetically the wine, to which they are incapable of communicating either taste or colour, and are not subject to the attacks of insects. For Champagne, which is always placed in corks, these offer great advantages. As Champagne is bottled after remaining at longest only three years in the cask, considerable deposit takes place in the bottle. When recorked this is got rid of, and the wine is thus rendered 

The neck; the cork is withdrawn, some of the wine rushes out, carrying before it the lees; the escape of the rest is hindered by an adroit adaptation of the fore-finger. To fill up the vacuole caused by a wine which has escaped, a solution of sugar-candy in any of the common red wines of the country is added: the permanent cork (or the caoutchouc stopper) is now introduced; when the latter, a simple but convenient piece of mechanism is used: it is then wired down, and finally covered with tin-foil. If preserved in a cool cellar, good Champagne may be kept in perfection ten or twenty years. In the great stores at Rheims the breakage amounts, on an average, to ten per cent. The Italian wines often have only olive-oil poured into the neck, being otherwise, without using a cork.

When ready for the consumer wine presents a combination of qualities which has always recommended it as one of the most agreeable beverages known. Yet wines differ much, not only in those nicer points which allure the research of the connoisseur, but also in those matters which are within his reach, and the quantitative analysis of which he can easily furnish. To give a full differential account of even the more common wines is impossible: a general view is all that can be attempted. Most wines contain the following substances, in greater or less proportion; the chief differences being the circumstance of the wine being a white or red one.

Wines are classified according to the predominance of certain of these ingredients. When much alcohol is present, they are termed strong or generous; when otherwise, light or weak; when much sugar undecomposed, sweet or luscious (vins de liqueur); when little, dry; if a free acid in considerable proportion be present, they are called acid or astringent; when much carbonic acid is present, then sparkling or effervescing (mousseux of the French, Schaumwein, German). Wine is more abundant in the wines made in wet seasons, and in the wine from new vineyards or young vines. These are also most prone to become sour. With the currents it was a great object to get rid of the watery portion, and for this purpose they employed various expedients, and often rendered the wine thick.

The plan now adopted by the French is best, to add starch-sugar to the must. The cheapness of this is not only recommendation, as it really is of the same nature a gravy.

**Alcohol.**—The amount of this principle present in wine has engaged the attention of chemists, who are now generally agreed that it exists from an early stage of the fermentation, and is not a product of distillation, as Baudez and Fabbri have supposed. It is also found that in naturally present, much brandy is too often introduced into wines intended for the English market. The table by Mr. Brande, of the quantity in different wines, is generally quoted; but recent analyses show that the amounts are much too high, probably from his having opened wines largely adulterated. The following table of Julia-Fontenelle and Professor Christison are more to be relied on, and agree better with that of Dr. Henderson.

The condition in which alcohol exists as the natural product of the primary and secondary fermentation of the grape is very different from that in which it is found when obtained by distillation, even of wine, as in the case of the finest French brandy. The addition of any distilled spirit to wine is always to be represented as improving the qualities of the wine, making it flat and mawkish. The much alcohol is not necessary to the keeping of wine is clear, since the Rhine wines keep for a century, yet in
these the quantity of alcohol is seldom more than eight or nine per cent. Dr. McColloch has forcibly pointed out the evils of adding brandy to wine in his ' Remarks,' p. 140: 'This practice, universal in the wines of Spain and Sicily which are intended for the English market, has also been introduced into our domestic wines, under the mistaken notion of preventing them turning sour, and with the idea that it enabled them to keep a longer time.' For the price of a brandy, it is procuring, if not adding. However slow the effects of this decomposition may appear, they are not the less certain. The first and most conspicuous effect is the loss of that undefinable lively or brisk flavour which all those who possess accuracy of taste can immediately perceive in wines or brandy, which is evident and a fairness, which must be sensible, by the principle of contrast, to the dullest palate which shall compare the taste of Claret with that of Port, or that of Hock or Grave with Lisbon or Bucellas. It tends equally, although in a greater length of time, to destroy the union of the colouring principle, which is well known to be deposited in Port wines, and apparently in a great measure from the action of this foreign substance. This fact explains why dishonest wine- makers are in the interest of the use of pure wine, much more particular in calling to this subject the attention of those who may engage in the manufacture of domestic wines, because a notion is prevalent that these wines are above all others deficient in durability, and cannot exist in a state of perfection that can be termed good wine, is to destroy the briskness of these wines, often the only meritorious quality they possess, while it increases their expense and diminishes their salability' (p. 158).

The method has been tried by the organs of the body in the same way as alcohol only diluted with an equivalent quantity of water. This is manifest even in the difference of the moral effects of unadulterated wine, in which the spirit is an integral element, and those of the colorless spirituous liquor. On many hands, a large portion of alcohol. The pure light wines of France and Germany produce an agreeable exhilaration of mind, very unlike the mere physical excitement, almost amounting to frenzy, which results from the largely branded wines, often to the amount of a fourth or even a third, it is most important that the facts above stated should be known to the consumers of wines, more particularly to females, who frequently imagine that they are taking something less objectionable in preferring these to the wines used by men. The light wines of France, of the Rhùne, the Moselle, or other itimitli and Marsanna of Spain, to which brandy is not added, are much to be commended, as more wholesome and not very much more expensive: at all events the health would gain where the purse suffers.

Sugar is the subject of a great importance, as it is to be feared that habits, at once discerrible and difficult to be relinquished, are contracted by women by the use of these highly stimulating mixtures:

1. If cointed these cordial silps to try;
   All feel the effect they send.

   For white omit of them they've all the force.
   And when denied, then drinks are the resource.—Crabb.

Sugar is the characteristic of the street wines. It diminishes with age, so that old wines of this sort are less pungent than the new. Some, such as those of Bergerac, lose their sweetness in six months, and become dry. They are mostly taken in small quantity as liqueurs; but still even in small quantity they are hurtful to persons disposed to the oxalic acid calculi, or to diabetes, and must be avoided. Bilious persons should abstain from them as from saccharine fluids.

They are more easily imitated than the dry and light wines; and at Cette in Languedoc there exists an establishment for it manufacture of an old known wine de liqueur. The Riverielles, Lemel, and Pronfian of France, the Puxarete, Tent, and Malaga of Spain, the original Malmeys of the Grecian Archipelago, that of Madeira, the Constantias, the Tokay, and Lachryma Christi, the Liss of Sicily, and many similar wines. Bitters, such as wormwood, are often used in them, which renders them less cloying and diminishes their tendency to derange the stomach.

Acids. It has been shown above that a free acid is necessary for the development of fungi (Saccharomyces) in which the progress of fermentation seems closely connected, for the evolution of the bouquet, for the agreeableness of the wine, and probably for its wholesomeness. It is therefore a popular error to deny them this effect, and to add it or destroy it. I think that this is however a very important point. Tartaric acid is the best. Whether malic acid be ever present in good pure wine is doubtful. It is said to prevail in wines made in wet seasons. Citric acid is found in this from unripe grapes. It is not certain that oxalic acid is ever found in wine. It may be formed in some rare instances. It is very likely however to exist in considerable quantity in the spurious wine now largely made from the garden rhubarb, and it must be hurtful. Acetic acid, or vinegary, is that however which mostly abounds in low poor wines, especially of northern countries, and in good wines which have been mismanaged and allowed to spoilt. The flav taste of the fluid and a smell among medical men. Dr. Prout (On Stones and Renal Diseases, 4th edit., p. 8) affirms that strong Sherry contains less acid and sugar than any other wine. But several very

P. C., No. 1728.
careful experiments on different wines by no means confirm this statement. If applied to Manzanilla, which is the favourite wine of the Spaniards, it is true; but that wine is scarcely known in this country, however well it deserves to be so, as its freedom from adventitious brandy and its comparative constancy of quality from year to year, a quality always to be prized in wines, strongly recommend it as a summer wine. It will be found that Port wine, both red and white, has less free acid than even some of the finest Sherries. Madeira, has long laboured under a just opprobrium in this respect. Bad Madeira, and the wine which, though produced elsewhere, was sold for it, contain much acid, and readily disagree with the stomach, may be perfectly true; but genuine first-rate Madeira has certainly very little, especially after a voyage to the East Indies. The Madeira wines had fallen off in quality from over-shipment, and thereby gave further effect to this taste for Sherry. In this a useful lesson was given to all wine-growing countries, as Madeira, although now as good, or rather, we should say better than ever, has not yet regained its former favour in this country. The observations of Dr. Paris are too just to be omitted:— 'What, for instance, is the acid contained in Madeira, and against which so many mighty objections have been urged? It is not consumed merely of Acetic Acid. And yet the person who fancies that his digestion can be deranged by its action, will swallow twenty times the quantity of the same ingredient in some other shape, with perfect indifference and impunity.' Before we quit, says the author, the subject of vinous acidity, I beg to say a few words upon its supposed influence in exciting paroxysms of gout. Such attacks have followed particular potations, I do not mean to deny; but a slight excess of any kind, whether in diet or exercise, will excite those paroxysms. In those cases supposed to be derived from the train is laid, an additional glass of Clarét may have acted as the match; but in all such cases the explosion would have equally taken place had, instead of Clarét, some other wine, which contained the same ingredient, been employed. Leibig unhesitatingly affirms that, while to the pre-eminent bouquet of the Rhine wines is owing, to the tartar present in them some of their most salutary properties belong. To this he attributes the immunity enjoyed by those on the Rhine and Moselle, in those lands where the esthetic principle, from the uric acid diathesis. This statement of the utility of these wines might be suspected to originate in national partiality; but it is abundantly confirmed by Dr. Prout and many others who have attended to the subject. But, it may, perhaps, be objected, that this occasional use of them is objectionable, but the habitual use is most salutary. (See Prout, 4th edit., p. 210.) Being light, they can be drunk without dilution, which is preferable to reducing a strong wine by adding water, or mixing it with a much more powerful poison, the diathesis, the stomach. In this respect the Rhine and Moselle wines are excellent in ten years, the Moselle is in six, and some of the clarets in four. Of sheries, Manzanilla is the fit for use in four years, so that the interest of capital thirty or forty years does not tend to increase its price. A wholesome beverage is not the only product of the grape. Brandy may be extracted from all kinds of wine, but more is drawn from some species than others. The strongest wines are not those which give the most spirit. It is more advantageous to distil wines which begin to decline, or become flat, from those which are perfect in flavour, because they are cheaper, and because the spirit in a more decomposed state is more susceptible of it. The wines which are made of coarse and rough produce brandy with difficulty. The sweet wines, if distilled, give little brandy. The more the wine is boiled in the heart of beygon, the better, being much used in commerce: the tartar is used in medicine and bleaching; and the dregs are dried, and serve the drier in the dyeing and the manufacture of hats.' (Pouget.) Vinegar is also prepared in large quantity from wine or its contents, even at Bordeaux. Wine is sometimes used as a substitute of medicinal substances; but as these are apt to spoil, pure spice or vinegar is preferred in many cases. (Henderson, History of Antient and Modern Wines.: Macloch, On Wine.; Pouget, Wines of Bordeaux.; Busby, Visit to the Vineyards of Spain and France.)

WINE AND SPIRIT TRADE.

The consumption of wine and spirits in the United Kingdom amounts in round numbers to about 28 million gallons, the duty on which, about £9,000,000, is equal to above one-sixth of the whole value of all goods imported into the United Kingdom. The average consumption of wine and spirits has been about 6 million gallons, though during the last three or four years, in consequence of the depressed state of the country, it has fallen very much below this quantity, and in 1841 the duty on less than 2 million gallons. Of foreign and colonial spirits the annual consumption is about 3½ million gallons; and of British spirits about 20 million gallons, though in 1842 it fell below this quantity from various causes. The stock of wine in bond is usually equal to two years' consumption. In January, 1843, the quantity under bond in the port of London was 7,074,547 gallons, and there were 4,450,246 gallons at the outports. At the same date there were 3,681,206 gallons of foreign and colonial spirits in bond, and 2,199,552 gallons of foreign and colonial wines. The duty on wines and spirits has had great influence on the public taste. In 1700 the average consumption of wine in England was nearly one gallon per head, whereas the rate of duty by the Methuen Treaty the wines consumed in this country were most entirely the produce of France, but although the duty on French wines was equalised in 1831, the annual consumption only amounts to one gallon amongst sixty people. In France the consumption of wine is 19 gallons per head and in Holland, with moderate duties, the consumption of foreign wine is one gallon per head. Mr. Porter states in 'Progress of the Nation, that there are wines produced in the United Kingdom that are superior in quality to the best French wines usually drunk here, and that they could be exported at sixpence a bottle without duty. If, as he remarks, wines of fair quality and flavour could be sold by nail at one shilling the bottle, the consumption would no doubt be very large, but the duty alone is at present not less than a shilling a bottle, and the consequence is that the consumption of French wines is chiefly confined to the more rich classes. As another illustration of the effect of high duties in checking consumption, it may be stated that the present duty of 20d. in the gallon on foreign spirits is twice as reductive than the duty of 1½d. in 1801; though if the use of consumption had followed the increase of population, the duty would have been 2,465,767d. more than it is amount actually received. The present rates of duty on foreign spirits have been fixed at 3d. from 2½ to 1825, according to the quantity; on rum from 200 to 400 per cent.; British spirits from 600 to 800 per cent.; Irish and Scotch malt spirits (whisky) 300 per cent. and upwards.

For many years the number of distillers in England has been reduced to twelve. In 1834 six distillers in London and the vicinity paid 1,030,292d. duty on 1,423,525 gallons, the tax being 7s. 6d. per gallon. The number of distillers in Scotland in the above year was 260, and there were 87 in Ireland; but the number of rectifiers in England, Scotland, and Ireland is a proof of the different state of the people in each country. In England, in 1838, there were 726 distillers and 11, and in Ireland only 50. It is very little brandy or rum is consumed either in Scotland or Ireland, the pure home spirit without any artificial flavouring being preferred. Nearly the whole of the spirit distilled in England passes through the hands of the rectifiers, and various ingredients are added to the spirit to give it the flavour resembling Geneva [GIN]; and above 500,000 gallons of English spirit are flavoured in imitation of French brandy. The simple spirit drunk in England under the name of whisky is imported from Scotland and Ireland. The number of gallons imported into England from Scotland in 1842 was 1,652,979, and 34,615 from Ireland. Malt and unaltered grain together are used in the English distilleries; six-sevenths of the Scotch spirits are made from malt, and the remainder from malt and unmalted grain; in Ireland about a tenth is from malt, and, with the exception of a hundred gallons in 1841, the remainder is from malt and unmalted grain. The number of gallons of spirits distilled in England, in 1842, was 6,098,456, in Scotland 7,058,859 gallons, in Ireland 5,315,090 gallons. In that year the duty was 7s. 6d. per gallon in England, 3s. 6d. in Scotland, and after March 11th, 1842, the duty in Ireland was increased from 2s. 6d. to 3s. 6d. The number of persons engaged in the various trades of distilling, complicating, and retailing, in 1840, was as follows:

</table>

In 1841 the consumption of British spirits was at the rate of 0.51 gallons per head in England, 2.28 gallons in Scotland, and 0.80 gallons in Ireland. Before the commencement of the temperance movement in Ireland, the quantity of consumption in that country was 1.75 gallons per head. The quantity of spirits charged with duty in Ireland fell from 12,206,432 gallons, in 1838, to 6,485,443, in 1841, the only change of duty being an addition of 5 per cent. The further diminished consumption in 1843-4 was attributed to the duty of 3s. 6d. a gallon led to illicit distillation. By this addition of a shilling a gallon duty, the minister anticipated an increased revenue of 250,000.; instead of which, in the year ending 5th April, 1843, there was a positive decrease of 7261.; the quantity of spirits brought to charge having fallen to 4,813,045 gallons, or 1,715,901 gallons less than in the previous year. On the 5th of April, 1841, the number of persons in gaol for illicit distillation was 48; on the same day in 1843 the number was 368. The financial mistake was so obvious that, in the session of 1843, an act was passed (6 & 7 Vict. c. 49) for returning to the old scale of duty.

The consumption of rum has been declining for many years in England, and is quite insignificant in Scotland and Ireland. [Not. With the same duty in each country the contribution per head to the revenue, in 1841, was 1s. 3d. in England, 2d. in Scotland, and 2d. in Ireland. In 1831, with nearly the same duty as 1841 (2s. instead of 3d.), it was 2s. 0d. in Scotland and 2s. 4d. in England and Ireland. The same rate of duty on foreign spirits, in 1841, yielded 1s. 7d. per head in England, 5d. in Scotland, and 6d. in Ireland. The quantity of all descriptions of wine consumed in the United Kingdom was about the same as 1841. In 1842, out of 100 gallons, there were consumed — of Portugal wines, 25-7 gallons; Spanish, 46-9; Madeira, 1-3; Teneriffe, 0-4; Sicilian, 8-1; Cape, 7-7; French, 7-4; Russian, 1-1. The consumption of the wines of Portugal was 25 per cent. of the total quantity half a century ago. [Post.]
WING, [Briz.]

WING, VINCENT, an English astronomer of the seven
teenth century, possessed some reputation during his life;
and his writings, at the time they were published, pos-
essed a certain value. Neither the year of his birth nor
of his death is known.

He is principally distinguished by his work (in Latin)
entitled 'Logica Astronomica,' which was published
in London in 1669. This is divided into five parts, of
which the first is designated 'Logica Astronomica;' the
second, 'Trigonometria;' the third, 'Doctrina Sphericas;' the
fourth, 'Theonis Planetarum;' and the fifth, 'Tabulae
Astronomicae.' All of these are added to a collection of
mathematical observations. His theory of the planets is founded
on the systems of Copernicus and Kepler, for he supposes
the orbits of the planets to be ellipses, and the sun to be
placed in a common focus; but, like Buitlalissus and Dr.
Sedley Ward, he considers the other focus of each orbit to
be the centre of the planet's mean or uniform motion.

The transit of Venus, which had been observed by Hor-
rox and Crabtree in 1639, indicated that the sun's parallax did
not exist, a few centuries before the evidence which was
afforded by some astronomers, at that time con-
sidered conclusive; and Wing, who supposed that the
parallax was equal to one minute (more than seven times
as great as it is in reality,) endeavoured to account, from
the then prevalent notion of uniformity of the earth's
motion, from an observation alluded to. The.

The astronomical observations in the work consist of several
luminaries of the sun at the times of the equinox, transits of
Mercury over the sun, and eclipses of the sun and moon, and
a conclusion: among these was the observation mentioned
in the previous paragraph; and it is stated
that at the time when the eclipse should have been total,
the moon was surrounded by a luminous crown
within which it appeared to turn on its centre like a mili-

The 'Logica Astronomica' contains a table of logistic
logarithms, with precepts for their use; and in the 'Trigo-

Wing published (in English) a work entitled 'Harmonicon Coeleste, or the Harmony of
the Visible World, containing an absolute and entire piece of
Astronomy.' It is similar in its arrangement to the 'Astro-
nomical Theory' of the preceding, but it contains
subjects which are not in the latter; and among these may
be cited his refutation of the ancient opinion that the
planets are attached to solid and transparent spheres.

He objects to the opinion on the ground that if it were just
the arrangement of the sun through the whole of
part of the solar system to another, and that the spheres
would produce great refractions in the light which is trans-
mitted to the earth from the fixed stars. The work con-
tains a table of the logarithms of the ten thousand first
numbers, and also of the sines and tangents of angles
for every minute of the quadrant.

It appears he has criticised the 'Astronomia Carolina,'
which was published by Stree in 1661, for the latter re-
plied in 1667 to his animadversions in a work containing,
asp printed in a few years, but the evidence which it
afforded was not, by some astronomers, at that time con-
sidered conclusive; and Wing, who supposed that the
parallax was equal to one minute (more than seven times
as great as it is in reality,) endeavoured to account, from
the then prevalent notion of uniformity of the earth's
motion, from an observation alluded to. The.

series, which in themselves are not simple, but again subdivided into similar and representative groups. The two great series to which they belong are the animal and vegetable *spherae*, as they have been designated: in the former of the forms of beings are mainly determined by the parts in which they are organically adapted; in the latter, by those of respiration and reproduction. If such analogy be true, we should see evidences of its truth on a comparison of the characteristic structures in analogous groups. Such evidence we perceive on comparison of the cells belonging to the animal and vegetable kingdom with those of the members of the vegetative (or articulate) sphere in the animal kingdom, of the leaf with the wing. There is no finer illustration of the relation of analogy in natural history, than that between the leaf of a plant and the wing of an insect. In both we have a double sheet of cells held together and strengthened by a framework of vessels, the structures of the respiratory system and the processes of the dermato-skeleton supplying the materials in each. Hence Oken has well applied to the wings of insects the name of *serial gills*.

Their anatomical structure has been well explained by Mr. Newport:—They are expanded portions of the common tegument of the sides of the meso- and meta-thorax, scutellum, and the supra-anal tinea, and of the parapleura, and the accompanying passages for the circulatory fluids, and their motions are intimately connected with the function of respiration. These tracheae ramify throughout the insect, and the gas cells of the tracheae are evolved by the assumption by the insect of the imago state, become solidified, like the rest of the skeleton. They are hollow, for the reception of air, like the proper respiratory organs within the body. They afford strength and lightness to the wings, with which they are united. Each segment of the flowers, the wings of birds, although the organs themselves in these classes are not analogous.  

They are distinctly seen," says the last-mentioned admirable observer," on the second or third day after the insect has assumed its last larva covering, before changing to the pupa state. They are then scarcely so large as the head of a moderate-sized pin, and appear like newly-formed folded portions of delicate tegument, extensively supplied with ramifications of minute air-vessels derived directly from the principal tracheae. They are at that time situated immediately beneath the cuticle, and situated between the parts of the sides of the meso- and meta-thoracic segments, and continue to increase in size during the growth of the larva. When the insect has discontinued to feed, about a day or two before changing into the pupa state, the future pupa is nearly completed beneath that of the larva, those rudiments of wings have become so much enlarged that their existence is distinctly indicated by the swollen appearance of the segments. It is at this period of the larva state that they were formerly discovered by Swammerdam. At the moment of fissuring the skin of the larva, they are suddenly somewhat enlarged; and when the skin has been cast off, and the delicate parts of the newly exposed naked pupa are beginning to be agglutinated together, they become solidified,

This drumming, or solidifying of the pupa case, they again acquire a considerable increase of size, owing to the extension and enlargement of the tracheal vessels within them, together with a corresponding increase in the quantity of the air with which they are expanded and invested. The wings are then expanded so as to cover the whole under-surface of the thorax and limbs; and when the insect subsequently bursts from the pupa case and is assuming the perfect state, they are again leaved out, netted, and expanded through the recurrence of similar phenomena."

The normal number of wings in insects is four, their position on the second and third segments of the thorax, and united to it by means of jointed and triangulating processes. The butterfly insects in the Dytiscid, certain *Hymenoptera* and Diptera, we find places of a third pair of wings. In others the number is apparently reduced to a single pair, but this is rather from a change in the form and character of the posterior wings than from their abrogation. As the habits of insects vary, equal powers of flight are essential in all the species, and as many are frequenters of situations in which the delicate textures of their wings are liable to injury, we find various modifications of their forms and structure, all to increase the circumstances under which the species is destined to pass its life. In a great number, such as the beetle tribes (Coleoptera), which live mostly on the ground and burrow in the earth or in wood, the anterior pair are hardened by the solidification of their membrane, and are as a result lost. In others the wings are reduced in size and shape, forming bodies called *halteres*, or poisers, shaped like a club, or presenting the appearance of a round ball on the extremity of a footstalk. Burmeister has been successful in making these muscles necessary to the insect during flight; for when he cut them out, the mutilated insects could fly but short distances. Burmeister has verified Schelver's experiments. Every fly which he deprived of its poisers lost the faculty of flight; it flew a short distance of two to three feet, but then rolled over and fell to the ground. If then it was urged, it made a fresh endeavour to fly, but failed in the same way.

The distribution and arrangement of the air-tubes, or air-nerves, in the wings is very various in the several families of insects, but so constant in each, that naturalists have found important characters upon them. There are two principal varieties of respiration in wings, reticulate and simple. An example of the first we see in the wing of the dragon-fly, where the principal nervures are situated together by others which are transverse, and often proceed at right angles from the larger ones, thus producing a beautiful netted aspect. Of the second kind the wing of the bee is an instance, where the nervures are simply anastomosing without being transverse. In the dragon-flies the arrangement of the nervures has been made use of by Jurine, St. Fargeau, and Shuckard as a valuable aid in classification. The last-named entomologist has given the names *angulata*, *fasciata*, and *punctulata*, so that the description of a wing is invested with a rigorous precision, of great consequence in the correct determination of species. Bowerbank has observed and described the circulation of the blood within the nervures. In the Orthoptera the production of sounds by certain of the species depends on the distribution of the nervures. At the inner angle of the base of each superior wing in the male *Acrida* there is a round, transparent, flat, nerveless space formed of tense membranes framed by strong nervures, which has been shown to be instrumental in producing the sounds for which that insect is remarkable. Burmeister explains its operation by means of the violent volatil motions which agitate the whole body, but during which the wings are expanded, the air is vibrated in the spicules, and especially out of the central ones of the thorax, and hence sounds against the infected external margin of the superior wing, which is pressed closely to the thorax. It is then necessary for the hind wings to fold the wing in order to escape from it beneath the posterior margin. Pursuing this path, it precisely strikes upon the just-described elastic field of the superior wing, which vibrates through the nature of the air, and hence emits the sound. This explanation does not seem sufficient; and in fact an important part of the structure is overlooked. M. Gourreau has shown that, besides the drum on the right elytron, there is a file or bow on the left. On the top of the left elytron, viewed from below, a
dilatation is seen, analogous to that of the right, but not so transparent. Its consistence appears to resemble that of the other portion of the elytron. What is most remarkable about it is a thick nervure striated like a file, which crosses it in a nearly parallel direction to its upper border, which I have named the bow.* (Essay on the Stridulations of Insects, translated in 'Entomological Magazine,' vol. v.) It is the action of this bow on the nervures and the tense drum which causes the sound. 'The males,' says Mr. Gourou, 'sing to call the females, and to please them. Three or four are sometimes collected together on the branches of some shrub, where they perform concerts in company, which, although they may not seem very harmonious to us, doubtless do so to the grasshoppers themselves. They appear to take great delight in this music and to emulate each other in singing. In these concerts it has been observed that the musical instruments are not all equally perfect; some give out acute and clear sounds, whilst others produce dull and harsh ones; this may be caused by some injury which the membrane of the drum has received; or from some defect in the bow, the teeth of which would be worn by long and frequent use.'

The chirping of the cricket is produced by a similar apparatus to that just described, one of the elytra being furnished with a bow and the other with a treble string; so that when they are crossed and rubbed against each other vibrations are excited and sounds are produced. The nervures which cross the elytra divide their surfaces into a great number of variously formed compartments, which have an audible vibration and a separate sound; the combination of all these little sounds produces the general sound or stridulation. When the insect crosses its wings rapidly, and passes the whole length of the bow over the treble string, it makes that loud and lively stridulation which we hear so frequently; and this is the very song with which he calls the female: but when he rubs the brush against the internal border of the elytron by a slight vibratory movement, he produces that sweet and soft sound by which he excites his sated mate. The sound must be artificially produced by rubbing the elytra together in a dead insect. A good account, with excellent figures of the sound-producing structures in Acrida and Acheta, may be found in Mr. Newport's excellent articles on the anatomy of insects, in the *Cyclopedia of Anatomy and Physiology.*

Whilst many species of insects have their wings smooth and naked, others have the surface more or less covered with hairs, spines, or scales, which in all cases are either projecting cells or layers of minute epidermal cells imbricated on each other. In certain species the hairs are converted into strong hooks or curved bristles, which lock the wings together, and thus aid the insect's powers of flight. The fine points of the wings of butterflies consist of scales of very beautiful forms and structure. The minuteness of these bodies may be conceived from the curious observations of Mr. Bowerbank, who, upon carefully measuring one of the dark-brown scales from the wing of *Papilio ursus*, that its greatest breadth was but \( \frac{1}{180} \) of an inch. The quill by which it had been attached to the wing was \( \frac{1}{480} \) of an inch in diameter; the distance of the strig upon its surface from each other \( \frac{1}{720} \) of an inch; and the diameter of the longitudinal strig themselves \( \frac{1}{840} \) of an inch. He found the scale of *Mivha* Méndelus to consist of at least two distinct layers; the uppermost formed of numerous longitudinal and cross striae, covered or connected by a thin membrane more or less coloured, and the under one composed of a somewhat thicker and stronger membrane, of uniform texture and without striæ.

The following table exhibits the relation of the forms and modifications of the wings of insects to the various orders into which they are grouped:

WINNIEP, LITTLE LAKE. [MISSISSIPPI RIVER]

"WININAM, JOHN, an ecclesiastical, whose name occurs very frequently in connection with the history of the Reformation in Scotland, but whose real influence in that struggle was not so great as to enable him to make a brief notice. He took the degree of B.A. at St. Andrew in 1515. In 1536 he was subprior of the monastery of St. Andrews. His first public appearance was at the trial of George Wishart [Wishart], where he pronounced the sentence. A singular duty for one who is said to have embraced the doctrines of the Reformation, and as singularly performed by his preaching, as appropriate to a trial of heresy, from the parable of the wheat and the tares. He both gained for himself and his church. He continued to hold office in the Roman Catholic church till the parliament of 1560, where, though sitting as prior of Portnoak, he appears to have voted for the 'Confession of Faith' which was then passed. On the establishment of the new polity in 1560, he appealed to the papal court, which had the sanction of the eastern districts. His influence in the new church was very considerable, but it appears to have been merely that of a dexterous intriguer, who knew when and how to gain the best effect to remove his support from a party he could not sufficiently reward his services. Knox, while accepting his aid, seemed always to have distrusted him. He died on 28th September, 1582."

(Wodrow, *Biographical Collections printed for the Man- land Club,* pp. 69-70, 711.)

WINCSLOW, JACQUES-BEIGNÉ, was born at Odes- see, a town in Denmark, in the island of Fünen, on the 9th of April, 1669. He was the nephew of the celebrated Stenon, and his father was a Lutheran minister in the parish of Odensee. Winsew was destined for the church, and early commenced his studies in Lutheranism. He however changed his mind and took to the study of medicine, and obtained a pension from the king of Den- mark for the purpose of enabling him to study medicine in the universities of Europe. He first went to Hol- land, where he studied for some time, and in 1668 he ar- rived in Paris. Here he became a pupil of the celebrated Duverney, who encouraged his taste for the study of anatomy. He pursued his medical studies without other interruption than an occasional dissertation on the subject of religion with a young Dane. Winslow for the sake of argument assumed the principles of Romanist,
and, to render himself more skilled, purchased Bossuet's
• Exposition of the Doctrine of the Church.' This work
led him seriously to question his own principles as a Pro-
testant, and as a consequence he recurred to Bossuet,
who was then widely read throughout, and whose
works, it appears, had been an act of sincere conviction
on the part of Winslow, and that he did not appear to have
my suspicion of the advantages that might be the result.

Whatever he expected in Paris, he forfeited in Den-
mark. He was invited to attend the meetings of the Academy,
and Meaux however became his patron, and he accordingly
proceeded to take his degree from the Faculty of Medicine
in Paris, which he did in 1706, but however until after the
death of his benefactor, who died in 1704. He had by
this time rendered himself favourably known by his ex-

In 1707 he was admitted a student of the Royal
Academy of Sciences of Paris, and afterwards an associate.

About this time he also assisted Duverney in his lectures
on anatomy, and the same time he did not however succeed to this position till after the
death of Fauquart, who was successor to Duverney, and which oc-
curred in 1743. Eleven years previous to this, Winslow
had published his great work on human anatomy, with the
title of, 'Les tentes et principes de l'anatomie humaine', Paris, 1732, 4to. This work obtained for him
at once a great reputation, and placed him among the best
anatomists of his day. This work is not more remarkable
in its elaboration of thelovers of another, and the clear manner
will win for him his readers, two days of astrono-
ungal observation which it contains. In the introductory
hapters to the description of each system of organs, he gives a general view of their functions, and in this de-
artment of science his judicious observations did much credit
to the science, especially in the description of the
functions of the muscular system. The 'Exposition'
has been often republished. It was translated into English,
dublished in London as early as after its publication as
1704, and also into Latin; and is the model on which most of our text-books
human anatomy have since been constructed.

Some of Winslow's biographers state that he was twice
early buried alive, by falling into a state of only apparent
decay, and buried in the earth of that time, of a cause of certain and uncertain death, and the result of his
searches he published in 1740, in an answer to the
section, 'An mortis incerta signa minus incerta à chirur-
diae quam ab albis experimentis? This treatise was tran-
slated into English, 1742, and published in London as early as after its publication as
1704, and also into Latin; and is the model on which most of our text-books
human anatomy have since been constructed.

In addition to his other appointments Winslow was made
appointed of the Teutonic languages at the Royal Library
of Paris. He was an active member of the Royal
academy, and published and papers on various sub-
cpts in their Memoirs. He practised medicine in Paris,
was remarkable for the timidity with which he pre-
mixed, and is said never to have ordered a powerful dose
of medicine. It is said that he was the first of the school of medicine that those who have studied the
human frame in detail have been afraid to treat it as
whole, and some of the best anatomists have been the best
practitioners. Winslow lived to the age of ninety-
ne, and held left behind him a son and a daughter.

Biog. Med.; Ely, Dict. Histo de la Médecine; Biog. Univ.)

WINSLOW. [Buckinghamshire.] WINSLOW, THOMAS, was born in 1755. He received his
education at Clare Hall, Cambridge, of which he became
a Fellow. He took his degree of Master of Arts in 1692. Having determined on studying medicine, he
visited the Continent, and attended the lectures of the most celebrated men of the day. He became a pupil of
Fabricius, of Aquapendente, also of Caspar Buhin of
Haute, and of Prosper Alpinus at Padua. He took his
degree of Doctor of Medicine at Padua, and returned to
London to practise his profession in 1697. He was then
admitted a Licentiate of the College of Physicians, and
became a Fellow in 1711. On the death of Dr. Moussel,
who was also a Fellow, he succeeded to his chair at
the College. It was here he delivered those lectures on
anatomy which after his death were published, and were
for a long time considered the best textbook for students
of anatomy. He obtained permission from the House of Lords
to leave the country during the troubles of 1642 and
returned after an absence of ten years. He died on the
24th of October, 1655. (Ward's Lives of the Gresham
Professors; Chalmers, Biog. Dict.)

WINOGRADSKAYA, NATALIA, was born in 1868. She
was the daughter of a Russian nobleman, and was
educated in Russia. She studied at the University of
the Leningrad and became a Professor of History and
Literature. She was a member of the Russian Academy of
Sciences and the Russian Academy of Education. She
wrote numerous works on Russian history and literature,
and was a pioneer in the field of women's studies.

wrote numerous works on Russian history and literature,
in 1752, and, even at the early age he had then attained, displayed himself his sagacity and courage.

Van Winter was still only a lieutenant in 1757, when the Revolution broke out in Holland. He attached himself to the popular party, and the adherents of the Stadthouder having gained the ascendency, he was obliged to fly to France where he joined the French army; served with dis- tinction under Dumourier and Pichegru, in the campaigns of 1792 and 1793; and was promoted to the rank of Ge- neral of Brigade.

Van Winter returned to Holland in 1796, when the repub- licans under Pichegru invaded that country. The States-General invited him to re-enter their navy, and offered him the rank of rear-admiral. Next year he was promoted to be vice-admiral, and placed in command of the Texel fleet.

After being kept in port for a considerable time by a su- perior blockading force, he evaded its vigilance, and put to sea, intending to join the French armament at Brest, on the 7th of October, 1797, at the head of twenty-seven armed vessels, fourteen of which were ships. At nine o'clock on the morning of the 11th, he found himself in the presence of the English fleet under Admiral Duncan, which consisted of sixteen ships of the line and a number of smaller vessels. The action commenced about 10 a.m. and continued till 11 p.m. On the 12th, the Vryheid (74 guns), Van Winter's ship, engaged with three English vessels, and struck to Vice-Admiral Onslow, after losing all its masts and the half of its crew. The Dutch lost in this action nine ships of the line, taken or destroyed, 600 men killed, and about 800 wounded. The loss on the side of the victorious English was scarcely less severe.

Van Winter was received in England with the respect due to a brave man. He was libered by exchange in a few months, and on the 11th October, the committee commissioned to examine into his conduct declared that he had maintained the honour of the flag of the Batavie republic. The despatch in which Admiral Duncan gave an account of the action bears testimony to the obstinate valour of Van Winter. In this action he performed under command (Vice-Admiral Reynettes) their ships—*The carriage on board the two ships which bore the ad- mirals' flags has been beyond all description.*

He was sent in the capacity of minister to the使团 of the French government in 1796, and retained the appointment till 1802, when he was recalled to take the command of the Dutch fleet. The only memorable event that marked his period of command was the termination of the obsequies between Holland and Tripoli by his manage- ment.

Louis Bonaparte, when king of Holland, reposed entire confidence in Van Winter, whom he created count of Hueca, marshal of the kingdom, and commander-in-chief both of the armed forces and land forces. He detached Holland into the empire, treated him with equal favour, made him grand-officer of the Legion of Honour and inspector-general of the shores of the North Sea. In July, 1811, Van Winter was appointed to command the naval force assembled at the Texel. A severe attack of sickness forced him to leave the fleet for Paris, where he died on the 2nd of June, 1812. He was buried in the Pantheon, with all the ceremonies usually observed at the obsequies of the great dignitaries of the empire; M. Marren delivered the funeral oration. (Biographie Universelle; London Gazette Extraordi- nary, 10th October, 1797.)

WINER, PETER VON, chapel-master to the king of Bavaria, knight of the Order of Merit, was born at Mannheim, in the year 1753. His father, a brigadier in the Palatine guards, observing his son's genius for music, placed him with the court musician, Mair, from whom he learned the rudiments of the art. His instrument being the violin, he completed his studies as a violinist, at the chamber of Williamramer (the father of J. B. and F. Kramer), who was first violin at the court of Mannheim from 1750 to 1770. With this excellent master he made such progress, that he became a performer in the editor's orchestra at the court of Mannheim, and speedily distinguished himself on other instruments.

It has been generally supposed, but erroneously it appears (Harmonicon, iv. 176), that Winter studied composition under the Abbé Vogler. He always denied this, and in a manner which indicated a strong dislike of the Abbé. He certainly had an aptitude for secrecy, and a very great respect for the name of Salieri of Vienna; but it is probable that he was more indebted to his own penetrating mind, directed to a careful examination of the scores of the great contemporary masters, to which he devoted much time, for his know- ledge, than to the instruction of any individual teacher.

In 1776, when Lessing carried into effect the establishment of a German opera at Mannheim, Winter was chosen director of the orchestra. He now first attempted com- position, and all his early efforts so decidedly failed, that he wisely communicated them to only a few intimate friends, and destroyed them nearly as soon as they were written, as example of wisdom which might have been most benef- icially followed by nineteen out of twenty of the day's composers, whose ill success may be, in many cases, compared to that of the first attempts which Winter displayed. In 1780 appeared his first complete opera, *Helena und Paris,* and this was followed by *Bellerophon.* He had brought out three ballads to *L'estéme Royale* the celebrated singer Hoffmann. His hint, induced him to listen and study more, and to write less. We therefore do not hear of his having produced anything worthy of notice till the year 1791, when he pro- ceeded to Italy, and at Naples composed *Antigone,* the *Iliadum,* and *Pyrrhus,* for the opposite seasons of the year, and for Venice. From 1794 to 1796 he resided at Vienna, where he produced some of his most effective works, and among these was *Das Unterbrochene Opferfest* (*The Inter- rupted Sacrifice*), the *libretto,* or text, of which was by his brother, and in which he displayed his power to fasten the place of residence, where he brought out *Il trionfo del Bel Sesio,* and *Maometto.* He was then invited to un- dertake the direction of the opera at Munich, for which he wrote his *Maria von Montalban.* Between 1796 and 1803 he produced his three finest works—*Calypso,* *Il Ratto del Prodigtio,* and *Zaira,* the chief characters in which were produced by Mrs. Billington and Madame Grasini. He here also brought forth the music of the grand ballet *la Fille du Pharaon,* and his second performance of mis- sing in the stage, unifying the energy and vivacity of pantomimic music with the char- telled regularity of that of the drams. From London he proceeded to Paris, and gave his *Tamerlano* at the *Théatre des Bouffes du Nord.* He was then persuaded to rest Quinault's *Castor et Pollux,* originally composed by Rameau. Gluck long before had de- clined this dangerous task, and Winter by undertaking it drew down on himself a storm from the admirers of the existing French opera, which induced him to abandon the same work was afterwards performed in London without success.

In 1814, the fiftieth year of Winter's service in the service of the Crown of Bavaria, the king bestowed on him the honour of knight of the order of the Holy Ghost, and a pension of 4000 francs. He continued to write and perform oratorio, and composed a number of songs, sonatas, quartets, and similar works. He died at Munich in 1825.

Winter's music was very prolific. His German biog- pher gives a list of nine masses and other religious and dramatic works; of operas and oratorios, of oratorios, symphonies, and other instrumental pieces, thirteen sets of cantatas, sonatas, together with numerous detached compositions, all of which he produced five years before his death; and to these must be added his instrumental works, subsequently to those composed. His early works did not exhibit much genius; but as he advanced in life his mind became gradually more vigorous, and his length developed a power which entitles him to be ranked very high as a composer for the stage and for the orche-
anthers. This ema—subcordate, has the W style diehotomous; is Harmonicon, the the whilst has they 5-celled, the the the Don's the corolla Opferfest, Zaira, introduced the programms of the Philharmonic and other concerts where good music is properly executed and well understood.

WINTER-ACONITE. [Eranthis.]

WINTER-BERRY, the name of the plants belonging to Prinos, a genus in the natural order Aquifoliaceae. The genus Prinos consists of shrubs with deciduous or permanent leaves, and solitary flowers. The flowers are mostly 2-celled, and often 5-celled, the styles deciduous. The fruit is generally a berry, or rarely a capsular fruit. The species are native to Europe. Among the species are: P. cyphus, P. decidualis, P. leucaphyllum, P. americanus, P. japonicus, P. japonicus americana, P. japonicus multiflorus, P. japonicus chinensis, P. japonicus japonicus, P. Spain, and Italy the berries are eaten by the peasant, and in some parts are made into pies.

P. pubescens, Downy Winter-cherry, is a branched herbaceous plant, clothed withomentum; the leaves are deciduous, acuminate, and sometimes unequal at the base; the corolla spotted; the anther violet coloured; the calyx permanent, ovate, acuminate, angular, and retuse at the base. It is a native of North America, in Virginia, the Carolinas, and Pennsylvania. The berries are yellowish-green colour, when ripe, and are used for making tarts.

P. somnifer a is a shrubby plant with glute entire leaves, which nearly sessile, at the base, or leaf base, inserted flowers the plant is a native of the East Indies, also of the south of Europe, in the Grecian Islands and in Spain. It has a yellowish-green corolla, and a small red berry. It appears to be the Συρίας ήσυχας of Dioscorides. Its name would lead to the supposition, that it possessed active narcotic properties, but of these little appears to be known, although it is not an uncommon plant in some districts of Europe.

P. viscosa, Clamy Winter-cherry, is a herbaceous plant, and scabrous from being covered with short dully three-forked hairs; the leaf is perfoliate, the petiole, the stem is dichotomous; the leaves ovate or subcordate, entire or toothed; the flowers almost spotted; the segments of the calyx unequal, broad, and ovate. This plant is a native of Brazil, and extends from Pennsylvania to the Carolinas in North America. It is so named from its being covered with forked bristles. It has a yellow berry, which is smooth and viscid, and has a pleasant acid taste. In most cases the fruit of Physalis has a bitter taste when ripe, which contains a minute projection. Many other species, as P. Persicaria, bear edible berries, and are reputed to possess medicinal properties, but they do not appear to be of an active kind.

WINTER-GREEN, the common name of the genus Pyrola and its allies, is given from the winter-berry, or the tribe Pyrole, of the order Ericaceae; but Lindley constitutes this tribe a distinct order, with the name Pyrolaceae. It has the following characters:—Calyx 5-leaved, persistent, inferior. Corolla monopetalous hypogynous, regular, deciduous, 4- or 5-celled, with an truncate corolla. Stamens hypogynous, twice as numerous as the divisions of the corolla; anthers two-celled, opening by pores. Ovary superior, 4 or 5-celled, many-seeded, with a hypogynous disk; style 1, deciduate; stigma slightly indented. Fruit capsule, 4- or 5-celled, with a central placenta. Seeds indefinite, minute, winged; embryo minute, at the base of a fleshly albumen. (Lindley, Nat. Syst.) The species are herbaceous plants, rarely shrubs. The majority of them are found in the montane districts of North America, but several of the species are also found in Europe, Asia, and Africa.

P. Alkengi, the Alkengi, or Common Winter-cherry, is a shrub, with the most simple stem ovate-celled acuminate leaves; spotless flowers; an ovate or round yellow calyx. The fruit is a yellowish berry, which has an acidulous flavour. The berries were known to the ancients, and the plant is described by Dioscorides under the name of Συρίας ήσυχας. The juice of the fruit was said to be of great repulse to scabs and administered in dropsy cases, and also in calculus disorders. In Germany, P. C., No. 1739.

Cladothamnus: calyx 5-parted; 5 petals; 10 stamens, with anthers adnate; stigma 5-lobed; capsule 5 or 6-valved, and 5 or 6-celled; seeds small and adhere.

Galax: calyx 5-parted; 5 petals; stamens united into a ten-toothed tube, the alternate teeth bearing anthers, the anthers l-celled; stigma entire; capsule 3-celled.

The species of these genera are natives of Europe, North America, and the northern parts of Asia. The following species may be taken as examples of the order:

Pyrula rodandofolia, Round-leaved Winter-green, has the stamens curved upwards; the style decline, arcuate at the apex; the petals obovate; the segments of the calyx lanceolate, acute, recurved at the apex, half the length of the corolla, and with equal racemes. This plant is a native of Asia, Europe, and North America. It is found in Great Britain, in the North of England and the Highlands of Scotland, but it is a rare plant. It has milk-white flowers and much leaves, and is the largest plant of the genus.

There are four other species of Pyrola natives of Great Britain; one of these, P. uniflora is only found in Scotland.

Pyrula aphylla, Leafless Winter-green, has no leaves, the scape is angular, and furnished with numerous scales at the base; the racemes are many-flowered; the petals are roundish and the disk of the stigma is elongated. This plant is a native of Nootka Island, on the north-west coast of America, where it was collected by Mr. Menzies. It is remarkable for having the approach of the genus to the characters of Monotropaceae. It has globose, pendulous, milk-white flowers, and the scales upon the scape are of a greenish colour.

The species of Pyrola are pretty plants in gardens, but they are very difficult to cultivate. They grow best in a sandy or gravelly soil, and in a shady situation. They should be surrounded by moss and covered with a hand-glass. They may be propagated by division.

Chimaephora is the Pyrola umbellata of Linnaeus. It is a native of Europe, Asia, and North America. It is a very bitter plant, and on that account has been introduced into medicine. [Chimaephora.] C. mocularata is a North American species, and found in sandy or alpine woods from Canada to the Carolinas, and on the north-west coast. It has lanceolate acute leaves, with white bands on the upper surface along the nerve and veins, placed opposite, or 4 in a whorl. The peduncles are duny and from 2 to 3-flowered. The Indians value this plant highly, and use it medicinally under the name of Spruce. Mr. Pursh recommended a decoction of this plant in cases of hysteria, and also in scrofulous diseases.

Moneres and Cladothamnus have each one species. M. grandifolia is a native of Europe, Asia, and North America. It is grown in alpine woods in the western parts of Europe, and in the island of Sitchn.

Galax is a genus of doubtful position. Lindley places it in Pyrolaceae; but, according to Snuff-gem, it is better to subsume it under Galaxaceae, as it bears the name of a distinct order Galaceae, and combines with it the genus Francoa, and Tetilla genera which constitute Jussieu's order Fraxineae. Galax has but one species, G. aphylla. It is a small herbaceous plant, a native of Virginia. It has naked scapes, which bear a loose spicate raceme of small white flowers at the apex. It is a pretty plant, worthy of cultivation, and may be grown in a pot soil in a moist situation, and increased by dividing the roots.

Galax umbellata is a natural order of plants belonging to the albuminous group of polypetalous Exogens. This order is characterized by possessing hermaphrodite or unisexual flowers; from 2 to 6 sepals, which are sometimes not to be distinguished from the petals; the petals are four in number and when more than five, in several rows; the stamens are hypogynous, short, indefinite, and distinct; the anthers adnate; the ovaries are definite, arranged in a single whorl, 1-celled, with simple sessile stigma; the fruit is either dry or succulent, and consists of a single row of carpels, which are distinct, and dehiscent or indehiscent; the seeds are solitary, or numerous, and either with or without an aril; the embryo is very small and straight, and situated at the base of a fleshy alburnus; the seeds consist of nutlets, or shrivelled; alternate, dotted, concave, persistent leaves; convolute, deciduous stipules; and solitary, sweet-scented, brown or chocolate-coloured flowers.

Illicium Chinarum.

I. cutting with flowers and leaves; 2, flower separated; 3, carpel.

This order has obtained its name, given it by Borrer from Wintera, the old name of the Drimys Wintera. This name was given in honour of William Winter, a captain in the Royal Navy, who sailed round the world with Sir Francis Drake. It contains four genera, which are distinguished:

Illicium. Capsules disposed in a stellate form, opening above, 1-seeded; seeds shining; calyx composed of 4 petal-like sepals.

Temus. Carpels two, baccate; seeds with an aificially single; calyx trifid.

Drimys. Carpels crowded, baccate, many-seeded; calyx united; stamens thickened at the top; calyx entire; three-parted.

Tsarnoma. Carpels solitary, membranous, indehiscent; many-seeded; calyx of three sepals, or three-parted.

These genera constitute the section Illiciaceæ of the order Magnoliaceæ of De Candolle. They differ from Magnolias in their dotted leaves and also in their aromatic qualities. A. de St. Hilaire states that some species of Michelia have dotted leaves, which destroys the distinction between these plants and those belonging to Magnoliaceæ. This order, though small, has an extensive geographical range. There are about ten species, of which two are found in New Holland, two in the hotter parts of America, two in South and two in North America, one in China and Japan, and one in New Zealand.

The following species of the genera are worthy of notice:

Illicium Floridanum, the Florida Anise-seed tree, bears from twenty-seven to thirty dark purple petals, the outer ones oblong and the inner ones lanceolate. It is native of West Florida. The leaves of this plant, when bruised, smell like anise, and the whole plant contains a volatile oil, which may be obtained by distillation. It has a spicy aromatic taste and smell, which in the plant is combined with a bitter principle.

Illicium amicinum, the Chinese Anise-seed tree, has from twenty-seven to thirty yellowish petals; the outer ones oblong, the inner ones linear and shaped. It is a shrub, like the last, reaching about eight feet in height, and is native of China and Japan, where it is frequently cultivated in gardens as an ornament. The fruit of this plant is known by the name of Chinese Anise, and is frequently
used as a condiment to give an agreeable aromatic flavour to certain dishes. It is the material used to flavour the liqueur called *Aristide de Bordeaux*. In China it is chewed after dinner as a stomachic and to soothe the breath. In the East Indies it is sometimes mixed with tea. In Japan the powdered bark is burned as incense in the temples, and garlands of the tree are placed upon the idols, and are also laid upon the tombs of the dead. There is also a popular belief that the fruit of *T. moschata* is a potent aphrodisiac.

*Teucrium moschata* is a shrub found in Chili. It has green shining leaves two inches long, and crowded upon the branches, with musk-scented flesh-coloured flowers having petals two or three inches long. The berries resemble those of the coffee-plant, and are exceedingly bitter to the taste.

**Drimys Winteri**, the true Winter's Bark, has oblong, obtuse leaves, the inner surface glaucous; the peduncles abutted in Laguncular. An Experimental and Enquiry on some properties of the tree, by Captain W. Winter, in the expedition of Sir Francis Drake round the world. He had found it useful against scurvy in his ship's crew, and employed it both as a medicine and a condiment for food. The bark which is met with in English commerce consists of the same materials as the genuine Winter's Bark; but is two inches in diameter. It is pale greyish-red externally, and has an agreeable pungent aromatic taste. It contains an acid resin, an acid volatile oil, and a little tannin. It is an excellent aromatic, but can seldom be met with in English shops. The essential oil of the *Crista alba* is often substituted for it. It is the Wintera aromatica of older botanists.

**Drimys Granatensis**, New Granada Winter-bark, has ovate-oblong or oblong acute leaves, tapering to the base and variegations in the under-surface of the leafy stems, umbellate, and usually aggregate at the tops of the branches. This is a tree about twenty feet high, and grows in the mountains of New Granada and Brazil. In New Granada this tree is called *Ag*; and in the provinces of Quito and Guayquil, *Winter's Bark*. Winter's Bark has been described. The bark of all of them is aromatic and stimulating, and is much used by the natives where they grow, both as a medicine and for seasoning their food.

There are three other species of Drimys possessing the same aromatic properties.

**Teucrium aromatica** is a native of New Holland, especially in Van Diemen's Land. It possesses the same aromatic qualities as the species of the other genera of the family. The only other New Holland species, *T. insipida*, does not exhibit the aromatic qualities the *T. aromatica* which are so striking in the first.

**WINTERHUR.** [ZURICH.]

**WINTERHEIM.** [SCHWAEB.]

**WINCHESTER, CLIFTON.** Father and son. The elder Clifton, Wincham practised as a physician at York, and published several works, which have obtained for him a reputation both as a physician and physiologist. His first work was on gout, and was published at York, with the title *Tractatus de Podagra, quo de ultimis et liquide et sucro nutritio tractatur*, 1714, 8vo. In this work there are evident indications of his belonging to the mechanical school. He attributed gout to several causes, such as the arthritic viscidness of the nervous liquid, the moon's influence, and to his own circumstances. In 1715 he published some observations on the diameter of the vessels near the joints. In 1718 he published *A Treatise on Endemic Diseases*. This work consists of an analysis of the causes producing endemic diseases, and attributes them variously to a change of the atmosphere, a strong wind, or the nature of the soil, to the influence of water and food, and particular climates. In 1729 he published a commentary on the epidemical diseases of York and its neighbourhood, with the title of the book *Commentarium nosophologicum morbos Epidemicos et contagiosos in urbe Eboracensi, locupietiam, vicibus, ad annum 1715 ad annum 1729 innumeris gradationibus complectens*. London, 1729. 8vo. This work is an admirable description of the diseases on which it treats. A second edition was published by the younger Wincham in 1733. In 1747 he published a second edition of his book *Parts of the Animal Structure*, 8vo. These inquiries were principally directed to the vascular system and the functions of the eye. In 1743 he published a second physiological work, entitled *An Enquiry into the Eality of the Vessels of a Human Body*, 8vo. In this work he has attempted to apply mathematical formulæ to the solution of physiological problems. But as the data upon which all the subsequent reasoning was based were mere assumptions, he came to no results of any importance; but these works, although not of much value, contain some valuable observations and valuable results. These works are often erroneously attributed to his son, and this error pervades most of the continental biographies. The elder Wincham was a fellow of the Royal Society, and died at York, on the 12th of May, 1744.

The younger Clifton Wincham was born at York in 1710, and was educated at Trinity College, Cambridge, and took his degree of professor of medicine in that university in 1740. He afterwards became a fellow of the College of Physicians, and settled in London. In the same year he was appointed physician to the Duke of Cumberland, and in 1762 was made physician to George III, by whom he was knighted. In 1759 he was made physician extraordinary, and subsequently was appointed physician general to the army. He was created a baronet in 1734, but the title has now become extinct. He had a large practice, and was much respected both in public and private life. In 1782 he published some essays on various departments of medicine in *De Commentarii*, 2 vols. 8vo. He also published an edition of his father's works, and added Mead's *Monita et Precepta Medica*, to which he added numerous annotations. There is a small marble bust of *Euscipius*, which was presented to this college by Sir John Wincham, of Cambridge, which was the bequest of Sir Clifton Wincham. He died at Hammersmith, on the 9th of January, 1794. (Eloy, *Dictionnaire Hist. de la Medicine; General Biographical Dictionary*).
Winwood, Kent, sometime one of the Principal Secretaries of State; comprehending likewise the negotiations of Sir Edmund Winstanley, Sir Nehemiah Crouch, Sir Charles Cavendish, Sir Thomas Edmonds, Mr. Trumbull, Mr. Cottington, and others, at the Courts of France and Spain, and in Holland, Venice, &c. Wherein the principal transactions of those times are faithfully related, and the policies and intrigues of the French and Spanish ambassadors, laid open to the world. The whole scene is drawn in an exact series of time. By Edmund Sawyer, of Lincoln's Inn, Esq., and one of the Masters in Chancery.'

(Biographia Britannica, Supplement)

WINZET, or WINGET, NINIAN, a Scottish ecclesiastic, is supposed to have been born in Lunenburg in the year 1518, and to have been educated at the university of Glasgow. In 1551 he was master of the grammar-school of Linlithgow, and soon afterwards, while he continued in that situation, he entered into holy orders. In 1561, on the establishment of the ecclesiastical power of the Reformation, he was cited before the Superintendent of the Lothians, to answer for his religious opinions, when, adhering to the doctrine of the Roman Catholic church, he was deposed from his office. In the following year he published "Certane" To the Church of Scotland, as a true and perfect defence of the Roman Catholic religion, and was, in consequence, excommunicated from the papal authority.

At a later period in the same year, and after Knox had addressed against him some controversial arguments from the pulpit, he attempted to publish a work called "The Last Word" against the usurp't authority of John Knox, and his Caluminae brethren, intrud' Prefecheouns, &c., but the Protestants had not made sufficient progress in religious toleration to have a free press at the disposal of their adversaries, and the copies of the work were seized in the printing-office. Winzet himself made a narrow escape, and the printer was imprisoned. The only fragment of this work which has survived to the present day is a copy of the first five leaves, preserved in the University Library of Edinburgh. The works of Winzet, thought it yurves, were refug'd in Flanders, and in 1563 he published at Antwerp 'The Buke of foucir thee Questions, touching Doctrine, Ordour, and Maneris.' This is a controversial tract, in which, though complaining of the usage he had received in the recesses of the country, he only subvers yair phantaisie and faction of faith, there is an air of gentleness which seems to have been peculiar to the disposition of the author, and is not characteristic of the controversial writings of the times. Winzet addressed himself to a different style of writing, and in his Scottish language he says to Knox, 'Gif ze, throw curiositie of novationis, hes forsoirt our auld plane Scots, quhill zour mother lerit zou, in tyms cuming I sally wryte to you mynd in Latin.'

Yet Winzet's own style shows nearly as great a divergence from the common way of writing of a century and a half after that of his master, though the latter made a nearer approach to the English of the sixteenth century. In 1576 Winzet was appointed abbot of the Scottish monastery of St. James', at Ratisbon. In 1592 he published 'Flagellum Sectatarum,' another controversial work, to which he added an attack on the 'De Jure Regni apud Scotos' of Buchanan, which is one of the earliest works in which the spirit of free inquiry then in operation as to religion was extended to politics. Winzet died on the 21st of September, 1592.

In 1794, a work, "Lives of Scottish Priests," i. 98-101: Memoir prefixed to Collection of Winzet's versified works, printed for the Maitland Club.

WIRE is metal elongated into the form of a slender cylinder. Sometimes it is so fine as to be termed, rather comparable to a thread, by the operation of wire-drawing, which consists in passing a piece of ductile metal through a series of holes, successively diminishing in diameter, in a hardened steel-plate called a draw-plate, so as to reduce its cross-section to the size and figure of the last or smallest hole, increasing its length at the same time in proportion to the diminution of thickness occasioned by the process. Though ordinary wire is cylindrical, the nature of the process of wire-drawing renders it available for the formation of any other required figure. An important application of the process to the production of other forms is to the manufacture of pinion-wire for timekeepers. This is produced of any required size and number of teeth, and the wire being cut to the required length, is first hardened, and then shaped to the form of the teeth required, by the portion used for the latter. By this means pins may be formed at much less expense than by the ordinary process of wheel-cutting. The grooved rims of spectacle-frames form another example of the useful application of the wire-drawing process, they being formed of wire made for the purpose.

Beckmann, in his 'History of Inventions and Discoveries,' devotes a long chapter to the history of wire-drawing, in which he observes that, in early times, metal rods were beaten out into wire; and the iron, brass, or copper, which were then divided into small slips by means of scissors or some other cutting instrument, these slips being subsequently rounded by a hammer and so as to form threads or wires. In confirmation of these remarks, he refers to the following passage from the account of Nahun, given in the third verse of the thirty-ninth chapter of Exodus, and to the fable of Vulcan forging a net of delicate wire-work for Mars and Venus, when detected by his illicit amour. He states distinctly that when this was first attempted, but argues that an allusion to gold and silver threads formed by the master in Muratori, that the process was not known in the time of Charlemagne, 'Nunc autem quo nos manentibus, ita dixit regin regis Nurnbergi, ubi in quibus, by the order of the emperor, the art of drawing wires had been invented, were styled 'wire-smiths,' but subse-quent the introduction of the drawing process their design was changed to 'wire-drawers,' or 'wire-millers,' and these appellations occur, as early as 1651, in the histories of Augsburg and Nurnberg respectively. Beckmann conceives that the invention of wire-drawing was assigned to the fourteenth century. In all probability the earliest drawn wire was made by hand, and was not disposed of the drawing wire without the intervention of hand, was introduced. Though the point is not certain, this ingenious machine appears to have first constructed at Nurnberg by a person named Esq., who kept it secret for some time, and only manufactured the use of it. Conrad Celtes, who wrote about the year 1535, relates these circumstances, and adds that the son of dolf was induced to divulge the secret, whereby he ascended his father that he was compelled to fly for his life to France. From this account it appears that the first wire-drawing machines were the pitch-pot and the pump, the year 1400. Nurnberg also gave birth to many quint improvements in the manufacture of various kinds of wire. The precious metals were undoubtedly the first made into wire; and perhaps brass and iron were the next. The wire machine that is generally mentioned is called a Engfrich, which is occasionally termed fil de Richard. Nothing however is known of Archal, and Menage suggests a different derivation for the name.

Anderson, under the year 1563, the granting of patents to certain Dutchmen or Germans for the procession in England of various manufactures, among which that of wire; and he states that prior to that time an English iron wire appears to have been drawn by hand, that strength, in the Forest of Dean, and elsewhere, and the quality of wire by foreigners brought the use of a drawing-wire and the quality of English wire was so bad that most of it was used in the country, as also was ready-made wool-cards and similar articles, was imported from abroad. By the year 1630, a manufactory for this particular wire was established, in a proclamation of Charles I. it is alluded to as a manufacture of long standing, and one which employed...
many thousands persons, and it is asserted "that English wire is made of the toughest and best Osmund iron, a native commodity of this kingdom, and is much better than what comes from foreign parts, especially for making wrougth-iron."

The proclamation then forbids the importation of foreign iron wire, and of wool-cards, hooks and eyes, and other articles made of it. Holland observes, that insignificant as hooks and eyes may appear, to be mentioned in a royal proclamation for strengthening the manufactures in a long previously, used in such great quantities as to cause a vast consumption of wire. Anderson subsequently states that the first wire-mill in England was set up at Sheen, near Richmond, by a Dutchman, in 1662. Holland observes that originally submitted to a quarter of an inch square, it is rounded on an anvil previous to elongation by the draw-plate. In whatever way the metal may have been prepared for the ultimate process of drawing, or what manner may be the motive-power employed in the process, it is essentially the same. The draw-plate is usually formed of a stony piece of shear-steel, about six inches long and an inch and a half in diameter, but being somewhat reduced in thickness toward the ends, like a cucumber, and flattened on one side. It is pierced transversely with several conical holes, the larger orifices of which open upon the flattened surface of the plate, while their smaller orifices are carefully finished to the size to which it is intended to reduce the wire. When the wire is fitted to, or tilted to a about a quarter of an inch square, it is rounded on an anvil previous to elongation by the draw-plate. The mode of preparing them a circumstantial account has been published by M. Du Hamel, whose directions are given at length by Holland, Hebert, and others. From the context, it appears that the French plates consist of a band or bar of wrought-iron, about two inches broad and one inch thick, covered on one side with a very hard composition called potin, which consists of fragments of cast-iron pots, broken wire, and charcoal. The broken iron and charcoal are exposed to heat until they are fused into a kind of paste, which is heated or fused ten or twelve times, and thrown into water to cool the tongues before by hammering. By this process the cast-iron is converted into a kind of steel, for yielding to the action of the hammer and the instrument by which the holes are enlarged and formed. One side of the wrought-iron bar is hammered to a furrowed surface, so as to produce a slight impression and to be covered, to the extent of about one-third of the width of the contrivance, by which the holes are reduced in size. The metal is reduced in the prepared potin; the whole is then wrapped up in a coarse cloth, which has been previously dipped in clay and water mixed to the consistency of cream, and finally put in the forge. Being more fusible than the wrought-iron, the metal is sooner reduced; and as soon as it begins to do so, the plate is withdrawn from the fire and gently hammered; and the heating and hammering are repeated alternately until the union of the two metals is complete, after which dry powdered clay is thrown upon the plate, for the purpose, it is said, of softening the potin. The plate is subsequently reheated, and extended by hammering to double its original length; the harder metal being so perfectly united with the other as to form a malleable alloy with it; and while the bar remains hot the holes are formed by the action of the hammer, and mixed with pieces of charcoal. In completing the holes, care should be taken to make them smaller and smaller by regular and almost imperceptible gradations, so that the work may not have to be reheated. After each of the holes is through by the plate-maker; the completion of the holes is then completed by drawing. Another mode of producing draw-plates, practised at one of the principal wire-manufactories in France, that of the Mouchel, at l'Aigle, in the department of the Oms, is by arranging several pieces of cast iron, or tin, with a lid, and filling the cavity with cast-steel. The whole is then covered with a hutting of clay, heated until the steel begins to melt, and worked in passing it backwards and forwards. For ordinary wire the rods are commonly reduced to a thickness of about one-eighth of an inch by this process. The slender rods thus produced are called, from their appearance, 'black wire,' to distinguish them from drawn or bright wire;' and, on account of its cheapness, such wire is preferred for coarse purposes in which it is either to be painted or concealed from view. It is commonly used by timber and joiners for the iron of a door or window, and various kinds of tin-ware and copper-ware, in which the tin-plate or sheet-copper is turned over or wrapped round the wire so as to cover it. The kind of cast-steel wire of which the best needles and some other articles are made, is not reduced in the above manner, but at a point slightly tilted to, or about a quarter of an inch square, it is rounded on an anvil previous to elongation by the draw-plate.
with a hammer in a similar way to that above described. When draw-plates have been hammered up several times, to reduce holes worn too large by use, they become so hard as to require annealing. For this purpose, a pair of cylindrical drawing plates will vary somewhat in hardness; but those which are too soft for drawing iron wire may be used for brass, while the very hardest are reserved for steel wire.

In drawing wire by hand the draw-plate is laid against two upright pillars fixed on a bench or table, and, the extreme end of the wire to be drawn being so reduced as to enable it readily to pass through the hole, a small portion is drawn through by a lever apparatus which resembles in its operation the mangle or rapping iron or rumpir, before described. When a sufficient length of wire has thus been brought through the plate, it is secured to a conical or cylindrical drum, which is mounted upon a vertical axis opposite to the hole in the draw-plate. The workman then holds one hand the coil of thick wire to be reduced, and the other a lever handle attached to the drum; and while he turns the drum so as to wind the wire upon its circumference, and consequently to draw it through the plate, it imparts a kind of twist to the wire which enters the plate, by a peculiar motion of the hand in which the coil is supported. In drawing coarse wire, which requires considerable power, the workman walks round the bench at each revolution of the drum, carrying the lever round with him; but for finer wire the apparatus is much lighter, being merely a few bricks, on which little injury is done the man power is used the winding-cylinders are turned by belv-gearing underneath the bench, and the coil of undrawn wire is placed on a reel. This apparatus is accompanied by an ingenious contrivance which allows the drum to fall out of the way of the wires, and with considerable ease to cease to revolve, as soon as the piece of wire is drawn completely through the plate. In some cases, as for pinion-wire, which would be injured by winding upon a drum, wire is drawn upon a long draw-bench in a straight line, the power, which is equalised by the use of a fly-wheel, being applied to a winch-handle which, by means of spurs, imparts motion to an horizontal rack.

Between the repeated drawings which are necessary to reduce wire, especially of the finer or smaller sizes, to the requisite form of tenacity, it is necessary to give heat and anneal it, by which processes the fibrous character imparted by the drawing is in some degree removed before a fresh extension takes place. The annealing-oven should be so contrived as to avoid oxidation as much as possible. While drawing, if small, the wire is wrapped into cards or into lengths of about a foot in formity, the thickest being placed in such a situation as to receive most heat; and after leaving it the wire must be secured or washed to free it from whatever oxide may have formed upon its surface. An improved furnace for this operation is the one described by Dr. Mouchel, is described by Holland. In order more perfectly to remove the oxide (which, if left on the surface, not only impairs the appearance and the strength of the wire, but also injures the draw-plate) the coil of wire is sometimes immersed in a bath of tar-red or state-beds during the operation of drawing. A curious and important discovery was made years since at an eminent wire-manufactory, where, in order to beat the acid liquor in which the annealed wire was steeped, some ingots of brass which happened to be in the vicinity for want of a more immediate use were made red-hot and used to heat and anneal the wire, by which process the fibrous character gained by the practice of the factory is in some degree removed. It was subsequently found that, owing to the action of the acid upon the brass, the iron wire had become coated with a thin film of copper, which greatly facilitated its passage through the draw-plate, acting, it would appear, like a lubricating medium. So important was the advantage gained, that the practice has been universally adopted in that factory of using a weak solution of copper in the acid liquor in which iron or steel wire is washed. The film of copper is entirely removed by the last annealing (which is also facilitated by the free use of grease, or, for the finer descriptions of wire, wax, to lubricate the wire as it passes through the plate. The repeated anneals of steel-wire would deprive it of too much of its carbon, but for the practice of it, which is not seldom employed, it would involve the formation of carbonaceous substance, so as to furnace. The rapidity of the drawing process must vary with the quality of the metal, the hardest steel wire requiring the slowest motion; but as each successive drawing increases the fibrous or filamentous character of the metal, the rapidity of the extension may be safely increased as the wire becomes more and more attenuated. Dr. Ure states that iron and brass wires 0.3 of an inch in diameter can be completely drawn to a thickness only 0.025 inch per second; but that when reduced to 0.025, or as an inch, they may be extended at the rate of 40 or 45 inches per second; while finer wire of silver and copper may be drawn out from 60 to 70 inches in a second.

Even when made with the aid of the coil of iron or steel draw-plates will enlarge so much with wear as to render it impossible to draw any great length of wire perfectly uniform in thickness. To remedy this, Mr. Brockedon obtained a patent in 1815 for a method of drawing iron wire, which consists of drawing on other hard precious stones. Dr. Ure states that with a plate of this kind mounted with a ruby, pierced with a hole 0.0033 of an inch in diameter, a silver wire 170 long has been drawn so perfectly uniform, that so different could be detected either by weighing portions of equal length or by measuring with a micrometer.

Dr. Wollaston communicated to the Royal Society, in the year 1813, a method of drawing wire of extreme tenacity, suitable for use in telescopes. This he accomplished, in the first instance, by boring or drining a metal wire, longitudinally, with a hole one-tenth of its diameter, and then filling it with gold. The compound being drawn into wire sixtieth or sixtieth of an inch in diameter, the silver was afterwards dissolved in bimetal of a small number of fatty acids, the wire is obtained perfectly round in diameter. Finding the operation of drilling the steel rod very troublesome, he subsequently drew platinum wire, and cast the silver round it, treating the compound before. The extreme ductility of the precious metals is still more readily increased by annealing, and consequent drawing, so that it is commonly known as gold wire, but which is really formed of silver gilt; actual gold wire being made only for framework and a few other purposes. In the ordinary mode of making gold wire a silver rod about an inch in diameter is covered with lead-gold, and then extended by a machine to obtain the required tenacity by successive drawings and annealings; the proportion of gold allowed to a pound of silver being seldom more than 140 grains, and sometimes as little as 100. Fine gold wire is used for wrapping or twisting in the preparation of some of the fine glasses of the optician. The gold wire is, according to the number given to the wire, of a corresponding size. An ingenious kind of gauge for showing the actual diameter of wire is represented in Holland's work, consisting of two straight steel rulers fixed together with their edges in contact at one end, and separated at about the half of their length, and the thickness of the wire to be measured brought between them.

The narrow triangular space thus left between the edges of the rulers will receive a wire of any size not exceeding half an inch in diameter, while a series of equal diameters marked along the edge of one ruler will afford a scale according to the number given to the wire of the corresponding size. An ingenious kind of gauge for showing the actual diameter of wire is represented in Holland's work, consisting of two straight steel rulers fixed together with their edges in contact at one end, and separated at about the half of their length, and the thickness of the wire to be measured brought between them. The narrow triangular space thus left between the edges of the rulers will receive a wire of any size not exceeding half an inch in diameter, while a series of equal diameters marked along the edge of one ruler will afford a scale according to the number given to the wire of the corresponding size. Among the many uses to which wire is applied in the manufacture of wire-gauze or cloth is peculiarly important the one which is devoted to the manufacture of knitting nets and sailings (vol. iv. pp. 309, 310, English edition of 1814) which expresses an opinion that the art of knitting with needle may have originated in an attempt to imitate some of the ingenious inventions of statesmen, and the employment of screens, and alludes to some very old specimens of wire net-work plaited or woven in so exquisite a manner as to give rise to the tradition that the artists who made them were enabled by infernal agency to accomplish that which appears too difficult for human
skill. Plainer kinds of weaving are performed by a modi-
cation of the common loom, the coarser varieties of
seven wire-work produced being used for fences, phac-
masaries, corse rods hedges, &c., while the finer sorts
are employed for lanterns, sieves, flour-dressing machines,
paper-making machinery, window-blinds, &c. The prop-
erty which renders wire-gauze so invaluable in the safety-
amp has been taken advantage of by the chevalier Aldini
for remedying the disorders of the human body, a process
which, though very light, is in a great measure flame-proof.
Wire-gauze is also formed into dish-covers, baskets, and
other useful and ornamental articles, by pressing it between
moulds into the required shape, which it retains perma-
nently. It has been manufactured in this kingdom and
patented in this country several years ago by Mr. Goessel,
of the Haymarket, London. After being pressed into the
required form, the articles are strengthened and neatly
finished off by the addition of hoops or rings to their edges
before they are removed from the mold. Much iron and
brass wire is used also for the manufacture of bird-cages,
feeders, and other articles of similar character. Needle-
making is one of the most important applications of steel
wire; but some of the finest sorts are made into spring
springs, in which form they receive an augmentation of
value beyond the prime-cost of the material probably un-
paralleled in the whole range of manufacturing industry.
Of the delicate hair-like springs alluded to, which weigh
only 30 grains to the pound; and it has been repeatedly stated, though perhaps
now the statement may be hardly correct, that the value
of such springs is half a guinea each; so that while a
pound of crude iron cost but one halfpenny, a pound of
these steel springs bring near 20 dollars. This kind of
work is of great antiquity, and was formerly much
employed for caskets, needle-cases, trinket-boxes, baskets,
shrines, and various decorations for church furniture; but
it has in a great measure fallen into disuse, as its present
use in lace and embroidery is much more elegant.
One of the most elegant applications
of gold and silver wire is to the production of Maggire
or Filigrane work, to form which, according to Beckmann,
'fine gold and silver wire, often curled or twisted in a ser-
pentine line,' is melted, and the solutions plated on
each other and soldered together so as to form festoons,
flowers, and various ornaments; and in many places also
they are frequently melted together by the blow-pipe into
little balls, by which means the threads are so entwined
as not to cause the leaves forming the ornament to
slide.

they are frequently melted together by the blow-pipe into
little balls, by which means the threads are so entwined
as not to cause the leaves forming the ornament to
slide. This kind of work is of great antiquity, and was formerly much
employed for caskets, needle-cases, trinket-boxes, baskets,
shrines, and various decorations for church furniture; but
it has in a great measure fallen into disuse, as its present
use in lace and embroidery is much more elegant.
One of the most elegant applications
of gold and silver wire is to the production of Maggire
or Filigrane work, to form which, according to Beckmann,
'fine gold and silver wire, often curled or twisted in a ser-
pentine line,' is melted, and the solutions plated on
each other and soldered together so as to form festoons,
flowers, and various ornaments; and in many places also
they are frequently melted together by the blow-pipe into
little balls, by which means the threads are so entwined

and on the north by gentle eminences covered with vines, protected from the bleak winds by the lofty wooded mountains beyond. In the immediate vicinity of the town there are productive gardens and orchards, and on every side neat farm houses and villages. Wisbech is open and comparatively improving town, and has broad and well-paved streets. This place owes its prosperity and its name, 'Baden,' to the celebrated hot springs, which were known to the Romans, and are spoken of by Pliny the Elder (Nat. Hist., xxii. 2.) Wisbech is on the site of a building called 'The Firkin Cross,' which was the butter market, the town having formerly had a considerable trade in butter, but the land in the neighbourhood is now nearly all under tillage, and the butter trade has consequently ceased. The market is chiefly for fish and poultry; one division of the upper part is the cheese-house, and the other division is the council-chamber of the burgesses.

The House of Correction was built in 1807. It has a tread-wheel erected at an expense of 600l., which acts as a flour-mill; the prisoners are generally about 30. In sessions-house, or shire-hall, is part of the same building, and in it the Lammans assesses and Midsummer and Epiphany sessions are held. The workhouse was formed in 1722, and is seated by 36 houses, at 2s. 6d. per week.

The town contains a large piece of ground called the green, the space on which the Castle, the barracks, and public buildings are erected. There are also several public charities in Wisbech, most of which were under the management of the corporation, but are now under trustees, according to the regulations of the Municipal Corporations Act.

There is a canal between Wisbech and Outwell, which was completed in 1792: it connects the Nene with the Ouse. Considerable sums have lately been expended in making the sluices at Wisbech, which is now river transport.

The navigation of the Nene to Wisbech had gradually become very difficult and dangerous, from the accumulation of mud and sand; but by cuts and other works has recently been much improved. The mills which used to force the water to the sea are no longer needed, and vessels can arrive at the quay of the port without material impediment. The vessels belonging to Wisbech in 1842 were 22 under 50 tons, of the total burtton 170 tons, and 56 above 50 tons, of the total burthen 436 tons. In 1841 the number of vessels which sailed coastways from the port were 840, total 39,317 tons; the number which entered the port were 1024, total 62,401 tons. In 1841 27 British and 15 foreign vessels, total 327 tons, of which 11 British and 3 foreign, total 58 tons, sailed for foreign ports. There is no colonial trade.

In 1840 the gross receipt of customs' duty was 8,981l.

The corporation, previous to the Municipal Corporations Act, consisted of ten capital burgesses, who were householders in the town. The burgesses were elected by the household freeholders. The whole number of the corporation, including the burgesses, in 1835, was 300, and the total population of the borough was 3,077. By the Municipal Reform Act Wisbech was divided into 2 wards, with
The Puget Sound, an inlet of the Pacific Ocean, is between the two great lakes lying east and north of it has been determined. Lake Michigan is 595 feet, and Lake Superior 627 feet above the Atlantic. The only point on the boundary between these countries begins on the shores of Lake Superior at the mouth of Pigeon River (48° N. lat.) and runs through a series of lakes connected with one another by short rivers westward to Rainy Lake and the Lake of the Woods. This river is formed by a meridian drawn from the south-western extremity of the Lake of the Woods to the Mississippi, which rivers it strikes below Lake Cass. Farther south the Mississippi divides Wisconsin from Iowa Territory. The area of Wisconsin is estimated at 95,000 square miles, or about 10,000 square miles more than Great Britain.

**Elevation of the Country.**—Wisconsin is more than 50 miles distant from the Atlantic in a straight line, and between 1070 and 1080 miles from the Juan de Fuca Sound, an inlet of the Pacific Ocean. The boundary line of the two great lakes lying east and north of it has been determined. Lake Michigan is 595 feet, and Lake Superior 627 feet above the Atlantic. The only point on the boundary between these countries begins on the shores of Lake Superior at the mouth of Pigeon River (48° N. lat.) and runs through a series of lakes connected with one another by short rivers westward to Rainy Lake and the Lake of the Woods. This river is formed by a meridian drawn from the south-western extremity of the Lake of the Woods to the Mississippi, which rivers it strikes below Lake Cass. Farther south the Mississippi divides Wisconsin from Iowa Territory. The area of Wisconsin is estimated at 95,000 square miles, or about 10,000 square miles more than Great Britain.

**VOL. XXVII. - B Q**
Sac River and the Big Rapids the country changes into a fine prairie; a considerable part of the eastern slope and the valley is formed by a small bottom of oak, ash, and maple. The soil, which farther north is sandy, has here more consistence, and it is supposed that it would produce small grain in abundance; the bottoms are rich and fit for corn and hay. The Big Rapids on the rivers and woods are still extensive, but in approaching St. Anthony’s Falls the country is entirely barren or a prairie with scarcely any timber, except some scrub oak. The bottoms are very small.

After descending the Falls of St. Anthony the Mississippi enters a region of limestone. It runs in a bottom, which below Lake Pepin widens from 4 to 12 miles. This bottom is uniformly bounded by limestone cliffs, which are generally abrupt and often precipitous. Within the bottoms, especially in the vicinity of Lake Pepin, isolated hills and knobs of considerable magnitude based upon horizontal strata of rock and towering to various heights are frequently met with. The valley consists of prairie and woodlands alternating; the former are usually elevated above the level of the prairie with numerous trees, flowers; the latter are generally formed by deep and numerous rivers and watercourses, which give to that part of the country a hilly and broken aspect. At the back of them the country is diversified by hills and valleys; the hills are high and rugged, and contain timber; the valleys often present extensive flats, abounding in lakes, swamps and ponds. The soil is sandy and the vegetation not vigorous; the trees do not attain their full growth. This country is bounded on the east by a ridge of hills, which, near 44° lat., is called the Oochoo and Smokey Mountains, and in the west by the Lake Superior region of the Ojibway Mountains. Their altitude is estimated at 1200 feet above the common level, or about 2000 feet above tide-water. This hilly region lies near 90° W. long., and there originate the head-water streams of a great number of rivers and numerous lakes. The current of this river is less broken and rugged, the soil is less sandy, the vegetation more luxuriant, and the forest trees attain a more stately growth. Large tracts in this part of Wisconsin are considered fit for cultivation. The forests on the Oochoo and Wisconsin are composed of white pine, pitch pine, and white pine of excellent quality, but white birch, white cedar, spruce, and juniper are also common.

The best known portion of Wisconsin is that which lies contiguous to the State of Illinois. The country between the Kaskaskia and the Wabash rivers, which runs from east to west, is an irregular plain, elevated from 250 to 300 feet above the surface of the Mississippi, and consists of limestone, which is often rent by deep and nearly perpendicular chasms of considerable depth but little width. On the upper surface of the prairie protrude several high single hills rising from 200 to 600 feet above their bases, and from 600 to 1000 feet above the watercourses which run in the chasms. The highest of these hills is called Arnot Hill, and is stated to be 1414 feet above the surface of the Mississippi at the mouth of Wisconsin River. The greater part of this region is a prairie destitute of wood, and generally covered with a good turf. There are also many tracts overgrown with trees, especially stunted oak, but little timber. The wood is usually covered by a black mould, which has frequently a depth of from 4 to 5 feet, and to appearance all the qualities of a fertile soil. But no part of it has been cultivated, agriculture being at present limited to the bottoms of the rivers. The country run at a considerable general level of the country, especially that of the Wisconsin, which resembles the bottom of the Mississippi, but is only from one mile to two miles wide.

The country along the shores of Lake Michigan has a different appearance, as far north as the small bay into which the river Michigan falls, but is limited by the great level and low plain which surrounds the southern extremity of the lake, and extends from St. Joseph’s River to the Waukegan. It is an extensive flat stretching far inland, with woods and swamps. The soil is apparently good, but the chilling northern winds which blow from the lake charged with vapour frequently spoil the crops. Farther north the shores of the lake are skirted by high sand-hills, which sometimes extend near and sometimes farther from the river, but probably form the country which is traversed by the Milwaukee and Waukesha Rivers, against the winds blowing from the lake. North of 44° lat. and up to Green Bay, and the boundary of Michigan, the shores of the lake are somewhat rocky, and the level soil on the sandhills is often too barren to be fertile; the country farther inland along the Fox River, and towards Winnebago Lake, has a considerable degree of fertility.

Rivers and Lakes.—The largest and most important are in the lake Michigan, in the western part of the State. Wisconsin, as the name of the country is derived, runs through the middle of the southern half. It flows from some lakes north of 45° lat., and runs first nearly 150 miles in a southern direction, when it turns to the south-west and west, and, after coursing a distance of 700 miles, it empties into Lake Michigan near Prairie du Chien. When swollen by a freshet it affords an easy navigation for boats of considerable burthen for more than 100 miles from Prairie du Chien to Lake Superior, and it changes its course into a south-western course. At this place is a portage of one mile and a half, across a flat meadow, which is occasionally subject to inundation, to the Fox River and Green Bay, thus affording a navigable connexion between Lake Michigan and the Mississippi, though the boats have been known to pass. The current in the lower part of the river is rapid, and like the Mississippi it contains numerous islands; when the water is low, the navigation is obstructed by shaws and sand-banks.

The Chippewa, a tributary of the Mississippi, upon its entrance, if of great magnitude, is the Fox River, whose head-waters lie to the east of the great bend of the Wisconsin. From the portage above-mentioned between the two rivers it runs northwest to a series of lakes extending from west to east. Issuing from these lakes the Fox River runs north almost 400 miles from the north by the largest of its affluents, the Wolf River. The united river passes through a small lake into Winnebago Lake, which is 30 miles long and nearly 20 miles across in the widest part. It leaves this lake north-westerly, and contains numerous chasms, and rapid streams which obstruct navigation, but do not interrupt the remainder of its course lies to the north-east, and falls into the most southern recesses of Green Bay. The navigable part of this river from the portage to its mouth consists of the, which is 300 miles long.

Of the other rivers we shall only mention three, which fall into the Mississippi, the Black River, the Chippewa and St. Croix Rivers, Black River drains a valley, in which the surrounding hills are covered with fine forest and contain the largest high plains of this part of the country, and from the north to the south is as large as St. Louis in Missouri. The Chippewa and St. Croix rise near some of the tributary streams of Lake Superior, and this circumstance has given them some commercial importance, as traders generally choose one of these rivers for their route.

The number of lakes which are dispersed over the country between the Mississippi River and Lake Superior is very great. In some parts they cover more than half the surface of the lake and the watercourses which give them a considerable influence; but there are also several larger lakes. The largest of these lakes of Woods, are the Plumeau Lake and Tomahawk Lake, which each of sends its waters to the Chippewa River. The country south of 45° contains the lakes of this part of the country which lies between the great bend of the Wisconsin River and Green Bay, and is drained by Fox River. This tract contains numerous lakes, among which is the Winnebago Lake.

Climate.—The winters are very cold and the summers very hot. The long and cold winters prevent wheat from succeeding in any part of Wisconsin, though the grain and plants which are sown in spring succeed very well.
The difference between the two seasons is much greater in the northern countries of Europe which are under the same degree of latitude and nearly as elevated as Wisconsin. This is evident from the subjoined table, which is founded on the several meteorological observations made at Fort Shelling, at the mouth of St. Peter's River, at Prairie du Chien, near the mouth of the Wisconsin, and at Fort Howard, at the mouth of Fox River. We add for the comparison the result of the meteorological observations made at Wexford, situated on the table-land of Smaland in southern Sweden.

**Monthly mean temperature of Fort Shelling, Prairie du Chien, Fort Howard, and Wexford.**

During the three winter months, and even in November, the cold in Wisconsin is so intense, that the thermometer frequently descends below zero, which very seldom takes place in Wisconsin; however the temperature rises rapidly in the month of March, much more so than in any part of Europe, and this seems to be the case in all parts of North America, but more especially in those west of the Appalachian Mountains, where the warmth increases more rapidly during March and April. Accordingly we find, that the spring is much warmer in these countries than in Europe, in places which have the same mean annual temperature. On the other hand, the decrease of heat in the months of October and November is also greater.

The best road to the interior is that situated near the shores of Lake Michigan are from the south-west for at least ten months in the year. But on the banks of the Mississippi the north-west is the prevailing wind, except in May and June, when the south-east is more frequent. At Fort Shelling however it is much more frequently replaced by a south-west wind. Thunder-storms are frequent, especially at the beginning of the spring and towards the end of the summer.

**Productions.**—As the number of agricultural settlements is small, and of very recent date, we are not yet fully acquainted with the agricultural productions that may be raised. Indian corn is said to succeed in a few places. Hitherto only oats and potatoes have been raised to any extent. In many of the numerous lakes and swamps which border the Lake Superior, and the British boundary, wild rice grows in abundance. It is collected by the native tribes, and used by the whites, who reside in these parts as traders.

The soil is fertile, and contains white, black, red, and post-cals, buckeye, walnut, sweet-pipe, lime-tree, cotton-wood, white, blue, and black ash, elm, red, maple, aspen, willow, elm, and the different kinds of pine before mentioned, white birch, and yellow cedar, spruce, and juniper. The prairies in the southern and western parts are covered with a fine turf, and afford good pastures for cattle and sheep.

Swine, and dairy cattle, have been introduced, appear to thrive. Cattle and sheep begin to be numerous. The terraces, which inhabit the northern districts, keep a few domestic animals, but the whites, who reside in the southern and western parts, keep but few, the number being of several kinds. In the northern districts are buffalo, elk, and deer in large numbers; but these animals are rare in the southern districts. Bears, wolves, and foxes are still numerous. The black and silver fox are greatly prized for their skins. The other animals are the bear, otter, mink, muskrat, and mink-rat, all of which are numerous only in the northern districts. The lakes, swamps, and rivers abound in water-fowl, such as swans, geese, ducks, and teal. There are also eagles, falcons, storks, wild turkeys, and partridges. Fish abound in the northern lakes. The river thermometer, which weighs from 4 to 6 pounds, and is very numerous in some of the northern lakes. The river abounds in sturgeon. Rattlesnakes occur, but they are not numerous.

The mineral riches of this country begin to be turned to account. It may be observed here, that it was discovered that in the southern districts of Wisconsin and the north-western corner of Illinois veins of lead occurred; and since that time the mines have been worked with great success. Their produce in 1829 had risen to thirteen millions and a half of pounds, and in 1839 to twenty-two millions. In the same part copper is found, and this metal has also been extracted, but not yet to any extent. At Mineral Point (42° 50' N. lat.) copper ore to the amount of 50,000 lbs. was shipped on the Mississippi for Swansea in 1838; and it is stated in the Report to Congress that this ore contained more than twice the quantity of metal which is contained in the ore obtained from the mines in Cornwall. The veins which yield copper ore contain besides quantities of zinc and calamine, of which however no use is made. Iron ore is also stated to be common, but it is not worked, and the small quantity which is consumed in the country is brought from Tennessee. There is also black lead, chalcedony, jasper, and corals. Good building stone is obtained from the limestone cliffs.

**Inhabitants and Population.**—Though the aboriginal tribes which once lived on the east of the Mississippi River have been removed to the countries west of it [North American Indians, vol. xxvi, p. 299], the tribes that have been established here still keep their footing in Wisconsin. Their removal was not necessary, as there is no agricultural settlement of the whites north of a line drawn from the mouth of Wisconsin River to Green Bay. In the northern districts of this country there are still copper, silver, and lead mines in the north-west and of Potawatomis; but the whole number of the Indian population probably falls short of 10,000 individuals. According to the census of 1840, the white population amounted to 30,540. Fenno, which was one-half of French and English origin. In the beginning of the last century, the French traders in furs had taken possession of the Island of Macoun Isaac, in the straits of that name, which unite Lake Michigan to Lake Huron, they discovered that Indian corn was raised in the southern part of the Wisconsin River; and accordingly they gradually settled small colonies at the mouth of the Fox River, on the portage between this river and the Wisconsin, and at the mouth of the last-mentioned river. The descendents of these traders turned to agriculture; and even after the beginning of the present century these Frenchmen were the only whites in Wisconsin who were agriculturists. Since that time the discovery of the lead mines has attracted many settlers from other parts of the United States. It is stated that about 2000 people are now settled in the mines.

**History, Government, Towns.**—Wisconsin was discovered by the French from Canada towards the end of the seventeenth century, as is related in 'Hennepin's Travels.' In 1836, when the French were expelled, the Spanish government was organized. The legislative assembly consists of a council of thirteen members, elected for four years, and a house of representatives of 25 members elected for two years. The governor, who is also superintendent of Indian affairs, is appointed by the federal government, and also the judges. At the country has only recently been settled, no towns have yet had time to rise. The seat of the government is at Madison, situated near the great bend of the Wisconsin; the seat of the county is Milwaukee, built at the mouth of the river of the same name, but it contained, in 1840, only 1712 inhabitants. Since the territorial government has been introduced, those districts in which several white settlers have been introduced, those districts are organized into counties, of which, in 1840, there were twenty-two. These counties occupy the tract which is south of the Wisconsin River.
along the Fox River up to its mouth, and the district watered by the Milwaukee River. The remainder of the country is not yet formed into counties.

WISCONSIN OP. [Jesus, Son of Sirach; Solomon, Wisdom op.]

WISE, MICHAEL, one of the most justly admired of our church composers, was born in Wiltshire, and was among the first set of Children of the Chapel-Royal at Westminster. He was chosen as the organist and master of the choristers in the cathedral of Salisbury in 1668. Seven years later he received the appointment of Gentleman of the Chapel-Royal; and in 1686 he added to his other offices that of almoner of St. Paul's Cathedral, including the mastership of the choristers. He was a great favourite of Charles II.; but it is said that, presuming too much on the notice of royalty, he incurred the king's displeasure, and was for some time suspended from his situation at court. The man says Sir Henry Wotton, was of a compleatness, and this, added to his high musical talents, may have recommended him to the favour of the "Merry Monarch." His end was tragical; for, quitting his house late at night in a state of great irritation, he was stopped by the police on the way from him entered into a quizzel, and was killed in the affray.

The compositions of Wise are among the glories of our cathedral music. He added melody to science, and in setting sacred words evinced a much judgment as genius. He composed, for instance, "Prepare ye, O Zion, the way of the Lord," and "The ways of Zion do mourn," have lost none of their charms by use or age, and are still listened to with admiration by all who hear them and whose feelings are attracted to church music of the most elegant and expressive kind.

WISEMAN, RICHARD, lived in the seventeenth century; he became first known as a surgeon during the civil wars of Charles I., and was the companion of Prince Charles when a fugitive in the Netherlands, England, and Scotland. He was afterwards a surgeon in the Spanish navy for three years, and returning to England, he was present at the battle of Worcester, where he was made prisoner. He was liberated in 1652, and then took up his residence in London. At the Restoration, Charles did not forget his companion, and he was made surgeon-surgeon to the king. He was an observant judicious surgeon, and his publications on various diseases were read by the profession with much acuteness. In this work he collected his views into one volume, and published them with the title, "Several Surgical Treatises on Tumours, Ulcers, Diseases of the Anus, Scrofula, Wounds, Gunshot-wounds, Fractures and Luxations, and Byphilis," 2 vols. 8vo. This work is remarkable for being one of the first attempts at the period in its kind, in which the subject was treated by one single eye to the advancement of medical science, he records everything that occurred, whether successful or unsuccessful, in the treatment of his cases. He suffered in early life for his attachment to royalty, and he will perhaps be excused on this ground, if his feelings are considered, for having advocated the efficacy of the royal touch in cases of scrofula. His works have always been considered valuable contributions to surgical knowledge, and the two volumes in which they are contained have gone through several editions. These treatises are the *Scrofula, Wounds, Gunshot-wounds, Fractures and Luxations, and Byphilis.*

WISHART, GEORGE, called "The Martyr," a champion of the Reformation in Scotland, is supposed to have been a son of James Wishart of Pitarrow, justice-clerk during the reign of James V. The time of his birth is not known. At the beginning of the sixteenth century he was master of a grammar-school at Montrose, where he introduced the study of Greek. Whether he ever took orders is a point undetermined. He began to diffuse the doctrines of the Reformation in Montrose, but being accused of heresy by the enemy which he roused, he fled to England. He preached the same doctrines at Bristol in 1538, but sterner measures seem to have been there adopted towards him, and he re- ceived and publicly burned his faggot. In 1543 he was at Cambridge. According to a notice of his character, apperence, and habits at that time, by his pupil Emery Tynley, he was a tall man, pale headed, and on the same a round French cap of the best. Judged of melancholy complexion by his physiognomy, black hair, long beard, comely of personage, well spoke after his country of Scotland, courteous, lowly, lowly, and did to talk of learning, and was well travelled. He is further described as charitable to the poor, and abstinent to the extent of austerity. In July, 1543 he returned to Scotland along with the commissioners who had been sent to England to treat for a marriage between Prince Charles and the Infanta, but the negotiations, brought on by the heads of the Reformation party, he now preached with boldness and fervour in Dundee, Perth, Montrose, and Ayr, creating popular tumults, which ended in the destruction of sixty of the Reformation churches in the counties of Angus and Fife. The English authorities with coming vengeance when they interfered with his proceedings. The limidlity which attended him while he was an obscure propagator of his opinions, even now that he exercised a wide influence on the popular mind and filled a large place in the eyes of noble men, to have been succeeded by a resolute spirit of defiance and a contempt of danger. The view which the impartial narrator must take of Wishart's character has lately been materially changed by the discovery of documents. A great part of the evidence against him has been dis- proof, that he was engaged in the plots against Cardinal Beaton's life. This charge, stated by two old Scottish biographical authors, Dempster and Dr. George Maitzen, whose accuracy is justly doubted, was repeated by a Roman Catholic historian, the Cardinal, and by a British Ht of Queen Mary, p. 40, and has been amply illustrated from original documents by Mr. Tytler. In a series of letters which show that there were several parties who were prepared to assassinate the author of the Act of Abjuration, the author of Henry VIII. to perpetrate the deed, and his promise of protection and reward, one signed by the earl of Hertford, Holgate bishop of Landaff, and Sir Ralph Sadler, and addressed to the king, dated 17th April, 1544, has been published; but according to the request, he have taken order for the open of the said Wyshart's papers, and that the delivere of such letters as he hath to your majesty from the said Brunstone, and also for the declaration of the said Brunstone, which, as I can perceive by him, consists in two poyntes: one is that the Lorde of Graeme, be- sauerd of Scotland, and the other that Charles the secon, and John Charters, wold attempt to pre- pend or see the cardinal at some tyme when he shal pass through the Pyfande, as he doth sundrye times. As for the first matter, sir Ralph Sadler said, 'this highnesse, repeting the fact as me to be set forward expressly by his majesty, will not seem to have to do in it, and yet not misliking the offer. In the end however the two persons whom Wishart was related to have been tried at the time when they were the memory of Beaton, the lord of Brunstone's house, four miles from Edinburgh. Venturing to preach in the town of Haddington, he took refuge with another supporter, Cockburn of Ormiston, in
whose house he was seized by the cardinal’s troops, and conveyed to St. Andrews. He was immediately put on trial for heresy before a special ecclesiastical council; Arran, the governor, having refused to give the predica- tions the countenance of the civil power. He was con- demned to be burned at the stake, and the sentence was executed at St. Andrews on the 28th of March, 1646, amid the portentous murmurs of the people.

It was a fully-fledged prophecy that tradition, as so often fulfilled; and his prophecy was one, that Bontoun should soon hang in igno- miny from the same window whence he was witnessing the execution; and the circumstances above detailed showed that he was a prophet from duteous lips, although without that event being without possessing the gift of prophecy. (Mackenzie, Lives of Scots Writers, iii. 9–19; Tytler, Hist. of Scotland, vol. v.; Lyon, Hist. of St. Andrews, ii. 1684–1696; McRie, Life of Knox, period ii.)

WISHART, George, an ecclesiastical and biographical writer, is said to have been born in Haddingtonshire, in 1609, and to have studied in the university of Edinburgh. In 1639 he was a clergyman in St. Andrews, when, refusing to take the covenant, he was deposed from the mini- stry. On 26th January, 1646, he is found petitioning the Scottish parliament as ‘sometimes minister at St. Andrews, and lastly at Newcastle, now prisoner in the common jail of Edinburgh, beggining to mortis, since he and his wife were accused of being Papists and heretics.’ He was, he says, ‘a young man, born 1609, and educated in the use of the law, and now reduced to the necessity of begging for the elegance of its Latinity. It was translated into English in 1652, and the author is supposed to have been the translator. There is in the Advocate’s Library a MS. continuation of the work to the death of Montrose, which has been conferred by the degree of Bachelor of Latin; but a translation of it was appended to a translation of the first part in 1720, and both were re-translated and published by Raddiman in 1756. A new edition of this translation was published at Edinburgh in 1810. After his patron’s death, Wishart became chaplain to Elizabeth, the Electress Palatine. At the Restoration he was made rector of Newcastle, and in 1662 was consecrated bishop of Edinburgh. Though he had himself suffered persecution, and in his writings was the advocate of, and at the same time the supporter of, the intolerant policy of Charles II’s govern- ment, and had recommended leniency to the Covenanters. He died in 1671. (Keith, Catalogue of the Bishops of Scotland; Lyon, Hist. of St. Andrews, i. 10–12.)

WISMAR, an important seaport in the grand-duchy of Mecklenburg-Schwerin, is situated in 53° 58’ N. lat. and 11° 58’ E. long., on a bay of the Baltic called the Wapich. It is surrounded with a wall and moat, and has four gates towards the land and four towards the harbour. The har- bour is very safe, but not deep enough for large vessels. Hempel however says, ‘the harbour is one of the best on the coast of the Baltic, not only having sufficient depth, but also being wide and commodious. In 1818, on the 25th of March, it was said of the road. It is a tolerably well-built town; the streets are in general straight, sufficiently broad, and ex- tremely well-paved. The houses in the principal streets are almost all of brick, but in general with the gable ends turned towards the sea. The town has the three churches, all in the Gothic style; the town-hall, a handsome modern edifice; the school-house, a very large and lofty stone building; the orphan asylum, and some other public buildings. The trade of Wismar, which had greatly declined with the revolution, has increased of late, and was, considerably increased in the last 30 years, though it is by no means to be compared with that of Rostock. Between 30 and 300 ships annually arrive and leave the harbour, which is a pilgrimage of importance. But Hempel (in 1837) complains that ‘the duties demand a florishing and secure maritime com- merce very difficult, and almost impossible. Besides the duties levied by the town, there is an import duty levied by the government, so that altogether the duties are double those paid at Rostock. The merchants of Wismar are still considered in the Mecklenburg customshouse as foreigners, so that they cannot compete with those of Rost- stock, and still less with those of Hamburg and Lübeck. Colonial produce imported by sea pays 5 per cent., whereas at Lübeck it pays only 1 per cent. It is therefore no won- der that the merchants of Rostock produce by land from Hamburg, Lübeck, and Rostock, by which they save at least 3 per cent., because they thus avoid import duty by sea, and have only to pay the town duty. The imports by sea are chiefly confined to Swedish productions, which are especially corn, fish, sugar, and tobacco, and the products of distilleries, tobacco manufactures, and some of linen and yarn; many of the inhabitants derive their subsistence from agriculture, and the fisheries in the Baltic. The exports are especially corn, but chiefly by Dutch ships; this privilege was induced by the countess of Mecklenburg, for the sake of some small capital which she had been allotted by Sweden, to which it had been assigned by the peace of Westphalia (1648), with its territory and the little island of Poe, to Mecklenburg Schwerin for 1,200,000 dollars banco.

WISTAR, CASPER, was born at New Jersey in America, where his father was a glass manufacturer, in the year 1776. His mother was a gentlemaness, and a member of the Society of Friends, of which society Wistat remained a member. He was educated in Philadelphia at the school founded by William Penn, and commenced his medical education in that city. In 1792 he received the degree of bachelor of medicine, and afterwards came to pursue his studies in Europe, and graduated in medicine at Edinburgh in 1796. His thesis was entitled ‘De Animo demissio.’ He returned to his own country in 1797, and when the college of Surgeons of Philadelphia was revived, he was appointed professor of chemistry and physiology, and delivered the courses of lectures on these subjects in 1789 and 1790. He was afterwards appointed to share the chairs of anatomy and surgery with Dr. Shippen and Dr. Shurtleff, and at the same time filled one of these chairs devoted on him. He was successively appointed physician and consulting physician to the dispensary, and physician to the hospital, of Philadelphia. In 1818 he was elected president of the American Philo- logical Society. He published several works on pharma- cine and anatomy: amongst others, Remarks on the Fever of 1783, and Memoirs on the Rhinum Bone, and on the Remains of an Animal belonging to the genus Bos.' In 1812 he published, in 2 vols. 8vo., A System of Anatomy, a work embracing the subjects, anatomical and physiologi- cal, which constituted his course of lectures in the college. He was very successful as a teacher, and his lectures were always well attended. He died on the 22d of November, 1838, which was the year in which he performed professional duties. He was married twice, and left behind him a widow and two children. (Encyclopaedia Americana.)

WISTARIA, a genus of plants belonging to the natural order Leguminosae, named by Nuttall in honour of Cas- par Wistar, professor of anatomy in the university of Penn- sylvania. This genus has the following character. The leaves are unevenly pinnate, and without stipules. The flowers are arranged in terminal racemes, and the lower the sepals are accompanied by bracts which fall off as the flowers expand. The calyx is cam- panulate, somewhat bilabiata, the upper lip has two short teeth, the lower lip three teeth, which are all diadelphous; a neck- tariferous tube girds the stipe of the ovary; the legume is coriaceous, 2-valved, l-celled, and rather torulose. The species are deciduous twining shrubs, natives of North America and China. They grow vigorously in Great Bri-
tain, and form when in flower the handsomest ornaments of our gardens. The following are the species:

1. **Arctomys (Spermochnus)**, New, Shrubby Wistarja, has the wings of the corolla such furnished with two auricles; the ovary glabrous; the flowers odoriferous. This is an elegant climbing plant, and is a native of Virginia, the Carolinas, and Illinois, in boggy places. The flowers open from July to September. They are of a bluish-purple colour, the standard having a greenish-yellow spot at the base. They give out a sweet scent.

2. **W. Chinesis**, Chinese Wistarja, has the wings of the corolla furnished with a margin; the ovary glabrous; the flowers large. This plant is a deciduous twiner, and is a native of China, and was introduced into this country in 1816. It flowers in Great Britain in May and June, and sometimes produces a second crop of flowers in August. The flowers are larger than in the last species, and are of a paler colour and hang in looser racemes. This plant is one of the most elegant additions that have been made to British gardens during this century. It was introduced into England by Captain Robert Webber and Captain Richard New, having formerly flourished in the plantations of Canton at the same time. The first plant that flowered was reared at the Rook's Nest near Godstone, in Surrey. From this plant the splendid specimen of this shrub which is now growing in the garden of the Horticultural Society at Chelsea, and a cutting has been planted against a wall 11 feet high, and the branches extend on each side of the trunk to a distance of nearly 100 feet. This plant, on account of its rapid growth and hardy habits, is getting very common in England, and will probably soon be regarded as the handsome flower of the season. This species was originally called *Glycine Chinesis*, a name which in some places it still retains.

3. **W. floribunda** is known by its glabrous stems and leaves, which are nearly round, and its hairy flowers. It is a native of Japan. It is represented as an elegant plant, but has not yet been introduced into the gardens of Europe.

The species of Wistarja are not difficult of cultivation; they are hardy climbers. They flourish most in a light rich soil, and should be trained against a south wall, which they will frequently cover with a profusion of blossoms. They may be propagated by cuttings or layers.

**WISTONWISH**, Arctoma (*Spermochnus*) Ludoviciana, is a species having procured in consequence of the different views of zoologists with reference to this animal, it becomes necessary to lay before the reader some of the descriptions and opinions extant concerning it.

**Description.**—A light dirty reddish-brown above, intermixed with some white and a forefoot and tail coat darkening to reddish, then bluish-white, then light reddish, then grey at the tip. Lower parts dirty white. Head wide and depressed above, eyes large, inner ear short and truncate; forefoot long and black; a few bristles projecting from the anterior portion of the superior orbit of the eye, and a few also from a wart on the cheek; nose somewhat sharp and compressed; hair of forelegs, throat, and neck not dusky at the base. Feet five-toed, covered with very short hair, armed with rather long black nails; external toe of forefoot nearly reaching the base of the next, middle toe half an inch long. Tail rather short, banded with brown at the tip, the hair, excepting near the body, not plumbeous at the base. Tail nearly equal in length, including the fur of the tail, 19 inches 4 lines.

Dark brown colour except their bellies, which are white; tails not so long as those of the grey squirrels, but shaped the same.

Head resembling the squirrel in every respect, except that the ear is shorter; tail like that of the ground-squirrel; toes long; fur fine, long hair grey. (Petit Chien.) Weight three pounds, colour uniform bright brick-red and grey, the former brighter; under side of the neck and belly lighter than other parts of the body; legs short, breast and shoulders wide; head short and muscular, terminating more bluntly, wider, and flatter than the common squirrel; ears short, having the appearance of amputation; jaw furnished with a pouch to contain and hold; tail of the common squirrel: five toes on each foot, the two outer much shorter than those of the forefeet, long, sharp, well adapted to digging and scratching. From extremity of nose to end of tail one foot five inches, of which tail occupies four. (Barking Squirrel, Lewis and Clark.)

Lewis and Clark makes of the Missouri and its tributaries.

This, according to Dr. Richardson, is the *Prairie dog* or *Gass*; *Prairie dog* or *Wistovitch* of Pike; *Petit chien*, *Prairie dog*, *Barking squirrel*, and *Burrowing squirrel* of Lewis and Clark, but not the *Burrowing squirrel* of the third volume; *Cynomys ludovicianus* of Old and Young. *Cynomys socialis et cinereus* of Rafinesque-Smalts; *Missouriensis* of Ward; *Arctomys latrans of Hale*; and *Prairie Marmot* of Godman.

This is the most that the best accounts of this animal, which has obtained the attention of all the apppellations since 1807, are given by Lieut. Pike and Captains Lewis and Clark. He further remarks that M. Rafinesque, considering the *Petit chien* briefly noticed by Lewis and Clark in their first volume, to be distinct from the *Prairie Squirrel* more fully described in their third, drew up from their notices the characters of his *Cynomys socialis et cinereus*. 'Dr. Harlan,' says Dr. Richardson, is continuation, has given the name of *Arctomys ludoviciana* to *Cynomys socialis et cinereus*, at the same time treating of the *Arctomys Ludoviciana* as a separate species. An alluring perusal of Lewis and Clark's narrative however has led the conclusion that in the passages cited above these travelers speak only of one species of *Marmot* under the name *Prairie dog*. They do not obtain a specimen, and its characters therefore have not been given. It is only at the time to the plains of the Saskatchewan, from the general colour of the animal, and from the description of its earth, it most probably was the *Twany Marmot* of the work. *Arctomys ludoviciana* of Murra, a rare animal confined to the *Spermochnus* of M. F. Cuvier; but the character given by the latter author are more precise and more distinctly drawn up.

Habits, &c.—Mr. Say states that this interesting animal has received the name of *Prairie dog* from a fancied resemblance of its warning cry to the barked warning of a small dog. The sound, according to him, may be imitated by the pronunciation of the syllable *chek, chok, chek!* in a slurred manner and in rapid succession: the breath, becoming the breath of the nose and the roof of the mouth. The assemblages of their burrows are denominated *Prairie-dog villages* by the hunters. They vary widely in extent: some are confined to a space of a few miles; others extend to a circumference of many miles, and are as large as towns. Many of these villages occurred between the Missouri and the Prairie towns; thence to the Platte they are much more numerous. He describes the entrance to the burrow as being surrounded by a number of the little mound of earth thrown up by the animal during its excavations. The excavation below, these mounds are sometimes inconspicuous, and generally somewhat elevated above the common surface; though rarely to the height of eighteen inches. Their face is that of a truncated cone, on a base of two or three feet, perforated by a comparatively large hole of entrance at the summit or in the side. The whole surface, continues Mr. Say, but more particularly the summit, is broken down and omelette, like a well-worn pathway. The sides descend vertically or to a gentle slope, and there, according to the various positions of the animal, it conveys down in an oblique direction. A single burrow may have many occupants. We have seen eight or seven individuals sitting upon one mound. The burrows occur usually at intervals of about twenty feet. They are used to sport about in the face of the plains in pleasant weather. At the approach of danger they retreat to their dens, or when its proximity is not too immediate, they remain barking and flourishing their tails on the further edge of the burrow, or sitting erect to recommence the fire upon in this situation they do not fail to escape, or if killed, instantly fall into their burrows, where they are beyond the reach of the hunter. As they pass the winter in a lethargic sleep, they lay up no provision of food for that season, and then they are not so large as when accurately closing up the entrance to the burrow. The further arrangements which the *Prairie dog* makes for its comfort and security are well worthy of attention. He constructs for himself a very neat globular cell with the...
dry grass, having an aperture at top large enough to admit
the finger, and so compactly formed that it might almost
be mistaken for a flower of the meadow.

Dr. Richardson observes that the Prairie dog seems to
differ from other American Marmots in the length of its
thumb-nail, and to approach in that respect A. Jules of
Lichtenstein.

WIT, a term which is applied to a faculty of the mind
and to the products of that faculty. As a faculty, it de-
notes not a distinct power, but certain specific modes of
using or operating upon the notions or images with which
the mind over the flimsy veil of the senses. The more
the more comprehensive faculty of imagination, with which
by early writers it was generally used as synonymous; they
sometimes used it in a sense still more general, as denot-
ing the intellectual faculty as distinguished from the will.
The precise boundaries of the term are still too un-
to admit of any strict definition. It may however be de-
scribed generally as consisting in the display of remote
resemblances between dissimilar objects, or such at least
as have no apparent resemblance. This species of wit is
exhibited in great perfection in two poems of a very oppo-
site class, the 'Hudibras' of Butler, and the 'Night
Thoughts' of Young; ludicrously by Butler, to display
the absurdities of 'hypocritical' pretence; seriously by
Young, to add force and point to his reasonings in favour
of his System of Ethics.

Other kinds of remote allusion, often without any actual
similitude, but suggestive to the mind, by indirect in-
ference, to make the comparison for itself, are considered
as wit, and produce a similar effect of surprise and plea-
sure.

When, instead of the remote resemblances discoverable
in things themselves, the different meanings of the same
word are brought into equivocal use, the operation is
called a pun. [Pun.]

WITCH-HAZEL. [WYCH-HAZEL.]

WITCHCRAFT. There is probably no age or country in
which there has not existed a belief in the possibility of
mortal beings acquiring the use of supernaturnal powers
for evil. Supposed to be a degree of that of a malevolent
desire, good or evil. In this, as in other species of super-
natural, there will be more or less resemblance in the
manifestations, wherever or whenever they are exempli-
ified, but that peculiar class of examples which comes
under the denomination of witchcraft admits of certain
lines of demarcation, which may be serviceable in keeping
the subject distinct from others. The proper field of this
superstition was among the Christian nations of Europe—
hence sorcery is more clearly defined than malevolence.
Maturity about the middle of the fifteenth century, and
flourished with tolerably equal vigour through Catholicism
and Protestantism, till it gradually decayed before the
progress of experimental science. In its doctrinal principles
it adhered to the idea of a connexion between the two
natures, being held to be a manifestation of the powers of
evil operating as antagonists to the authority of the Deity.
It was not necessarily used to accomplish evil ends, because
so many of the accusations of witchcraft relate to acts which
are condemned by no known moral code, but which became crimes from the means made use of. The
powers of evil thus employed by human beings had their
personal embodiment either in the Prince of Darkness in-
dividually, or in certain subordinate agents called imps or
sorcerers. In some cases the creature believed to be the party,
who, in one of their evil purposes to convey in remainder, for what was given to him according to their own desire. Besides the bargain in which the parties are
posed to covenant openly with each other, each party
usually presumed to have in view the secondary object
that every application of the doctrine of Covenant,
which recurrence have dealt largely in the horrors
resulting these mental efforts of imposition, where the one
striving to recover his chances of eternal salva-
tion is to be required to make concessions and promises
by the other to bridge the promised rewards, or to
return the donation of their enjoyment. In the most sin-

aspect the struggles of the evil one to cheat his victim are
exemplified in the ordinary Scotch superstition that he
transfers them money, which is then returned, and by
the sin of theft into slates or other rubbish; and the same instance is given
by way of example by Biensfeldius, a German author, who in
1591 published 'Tractatus de Confessionibus Malefi-
corum.' This author, who is one of the most systematic
of the numerous writers on this subject, declares that, instead
of venting the indignation of an excited and terrified
mind against the lost agents of infernal power, treats all
the horrors of sorcery with the gravity of an analytical
philosopher,—tells us that there are three elements nec-
essary to the accomplishment of witchcraft; thus:—shutting
permitting it; the power of the devil instigating and as-
sisting the operation; and man's corrupt will consenting
to be the instrument. It is a further general characteristic
of the superstition that the comment of the layman, or
the agents or victims have, in the majority of cases,
been females; and that in later times, when the charac-
ter of the superstition had degenerated both in the mag-
nitude of the objects accomplished and the rank of the
actors, witchcraft came to be considered a power exclu-
sively possessed by old women. It is probable that a pro-
cessingly to attribute the faculty of divination and the art
of perpetrating supernatural mischief to females may have
legitimately descended from the Pythia of the more early
periods of Roman history; and that the account of the witch
of Endor may have tended to strengthen the opinion. In
the superstitions however of nations which have had no
knowledge of acquiring power from the use of the
African Negroes, the North American Indians, and the Scan-
dinavians anterior to their adoption of Christianity—females
seem to have always been the prominent agents in the appli-
cation of the minor supernatural influences. In the prac-
tice of witchcraft within the limits assigned in this
article, it might be possible to find, in the nature of the
connection between the supernatural being and the earthly
agent, a tolerably sufficient reason why the influence of a
female must generally be greater in the infernal court
than of a male. It is observable in the records of the trials for witchcraft, or the books in which the subject is most minutely investigated, will observe how
necessarily it must follow that the power of evil being
endowed with the masculine gender, and committing its
sex to those spiritual emanations of his power which some-
times in his stead do his bidding upon earth, the mortal
recipients of his malignant influence must necessarily be of a
different sex. The institutional writers on the subject
seem to have considered the male of the species as not for
such purposes; consequently they lay it down as a general principle that women are
more liable to be the agents of Satan than men, a circum-
cance which Spranger, in his 'Maleus Maleficarum,' traces to what he calls their inferiority in mental strength,
and to their infirmity in moral character.

In going back to an earlier period than that which is
here assigned as the time when the superstition of witch-
craft was full grown, it will be found that the accusations
of nearly resembling the more modern offence of witch-
craft are of two distinct kinds—attempt to accomplish
mischief through the operation of poison or other natural
agents, and lapses from Christianity into heathen practices.
The Anglo-Saxon laws against sorcery or witchcraft are
simply levied against the practices connected with the
heathen worship from which the people had not been long
converted. The corresponding accusations in the south
of Europe are levelled against intercourse with demons who
represent Diana and her nymphs or Pan and his satyrs:
thus making visible the origin of the last described
act. In the south, however, we find the same personages
offering with changed names, and with natures adjusted to the religious opinions
of the age. The secrecy with which the Waldensians and
other early sects from the church, or group, endeavored to hold their opinions hidden away,
besides upon them charges of indulging in such unhallowed rites as were
traditionally considered the characteristics of ancient
heathenism. The horrors of the witchcraft superstition,
therefore, may be said to have had their birth among the
convertibles, and in the same charges are made against those
who frequented them in the thirteenth century which
we find made against witches in Sweden and Scotland in
the seventeenth. One remarkable practice of which the Wal-
densians accused will be recognized by every school-
boy who has heard a witch legend in the nursery—they were called 'scabbes,' because they rode to their meetings on a scab, or broom. The 'Narrative of the Proceedings against Dame Alice Ayscough, Prosecuted for Sorcery in 1324,' edited by Mr. Wright, for the Camden Society, and which is perhaps still more curious from the light it throws on the early conflicts between the ecclesiastical and the civil power, than in its reference to this subject, was published both as the classes of offences here alluded to. She was charged with having prepared noxious compounds, productive of debilitation which ended in death, and also with abjuring her belief in the holy church, with having deserted the mass and the eucharist, with having sacrificed in her own chamber, and with having attempted to undo the keys of the Church by imiously imitating the ceremony of excommunication.

During its earlier stages, the art of witchcraft was in far higher hands than those to which it afterwards descended, and was used for greater purposes. Witchcraft or sorcery was the means by which Joan of Arc was charged with having obtained her power as a warrior. The duchess of Gloucester was banished to the Isle of Man for sorcery against Henry VI. Richard III. made repeated accusations of the duchess of Berwick, that Bevis of Monmouth was under her fell influence against Jane Shore. The earliest witch trials in Scotland generally implicate persons of rank. Sometimes the women who are accused are young, and they do not always use their power for mischievous and malicious purposes. Bevis of Monmouth, who was tried in 1576, appears to have used her art for no other purpose than the cure of diseases and the performance of other benevolent acts, accomplishing them through the instrumentality, not of Satan or any of his emissaries, as was the case in the prosecutions of witches centuries later, but through the aid of an amiable old gentleman, who had the misfortune to be a prisoner among the fairies in Elftand. Alesoun Pearson, tried in 1588, had a long intercourse with Elftand, which appears to have commenced when she was not too old. She and many other persons among the fairies there, one of whom was her cousin William Symson, a doctor of medicine and 'one great scholar.' She was in the practice of appealing to her friends in fairyland for the means of curing earthly diseases, and Archbishop Abbott did not disdain to follow up the subscription which she obtained for him, his reliance on it being probably not weakened by his acquaintance with the virtues of the principal ingredients, which was claret.

These two trials so far exhibit the darker characteristics of the rural ceremonies, that Heinie the banisher from Elftand wished her to put her soul in his possession; and Alesoun Pearson was told that of the fairy host the tithe is taken every year to hell. The method in which the same occurrences are mentioned by writers of different times shows the progress of the authorities of witchcraft; and, as may be afterwards more particularly mentioned, both in England and Scotland the investigations of King James did much to explain and clear the misunderstandings of his day; to raise those who were so withered and so wild in their attire, that look not like the inhabitants o' the earth, and yet are o't. Perhaps the latest conspicuous occasion in which rank and beauty have been allied with charges of the nature of witchcraft, is that of Mrs. Wright and Mrs. Thomas, in the magnificent person of Sir Thomas Overbury and the practices against the earl of Essex; but the direct and palpable crimes exhibited in this horrible history throw the attempts at evil through supernatural influences into the shade. When in later ages it ceased to be encouraged by the great and the learned, witchcraft degenerated, till, in the end of the seventeenth and the beginning of the eighteenth centuries, it was entirely confined to such persons as Harriot so early as 1560 described a poor beaten crane, having her chin and her knees setting for age, walking like a bow leaning on a staff, hollow-eyed, un-
assassists who had not the means of ornamenting their writings with some of the wisdom of the antients. Jonson says he remembers some such figures having been dug up in a dunghill in his youth. The story of Bolingbroke and the witch of Eye, in Fabian's 'Chronicle,' illustrates this practice. In Middleton's 'Witch,' Hecate says, 'Is the heart of wax stuck full of magic needles?' King James, in his 'Dramatic Poems,' said that the life was a fiction of the operation of this charlatan; and after receiving so high a sanction, it of course cuts a conspicuous figure in the subsequent witch trials both of England and Scotland. In the latter country it became united with a belief in the uneartly origin of the operations, whom he describes as resembling the life which was familiar in the witchcraft^ the metamorphosis was made known by a charge being brought against the individual of having assaulted and wounded some women of rank in the neighbourhood, when he disclosed the fashion in which they had appeared, and the affair was hushed up. In the same work (p. 292) there is another instance, the same in its essential particulars, quoted from Bodinus. A belief in the metamorphoses of human beings into brutes is a superstition so widely exemplified in classical literature, and in the sculpture and paintings of all societies of men sufficiently civilized to provide such testimonies of their customs and belief, that it cannot be assigned as a special feature of the belief in witchcraft. The wildest however of the vagaries exhibited in the above, and discoverable in many like cases, seems to us to be the belief of the French in the metamorphosis to leave no other alternative but the belief, that the doctrines promulgated in one part of the world were in all their minute particulars adopted in another. This extension of, or the corruption of, the tales, was so prevalent a belief in France and Germany as to be the subject of separate treatises and of various judicial inquiries. It naturally did not extend to Britain. This superstition may be perhaps more distinctly traced to the influence of witchcraft than to any other single cause. As we are in this work chiefly concerned with this subject: by the Greek physicians it is understood to have been treated as a disease. Both the English and Scottish trials frequently illustrate the power supposed to be possessed by those in league with Satan of converting their victims into brutes, which they accordingly employ to convey them to the scenes of their unhallowed assemblies. This feat was performed on a large scale by the great army of witches charged with assembling at Bloomsbury in Sweden, in 1668, according to the narrative of Glanvil, in 'Sadoceismus destructus.'

A power over the elements is one of those gifts with which superstition will be most likely to invest its invisible agents. In its less striking form it has the aspect of a malign interference with the ordinary course of nature, by blasting some particular district, or transferring its elements of fruitfulness that they may increase the produce of some other tract in which the sorcerer is interested. This species of incantation is prohibited by the Twelve Tables (Dirksen, 'Uebersicht, &c. der Zaubertafel-Fragmente,' p. 539), and the illustrations of it in the witch trials are too numerous to be mentioned. A trading or maritime population living on a stormy coast will endow their malignant demons with a more awefull authority over the winds and waves. Olaus Magnus treats largely of the storm-raising powers of the Scandinavians. It was on his return from these regions with his wife Anne of Denmark, that King James produced so goodly an array of accusations against witches for aiming against his life; and among certain of the American witch trials of the seventeenth century, the aspect of superstition was prevalent, it is natural that the aspect assumed by the accusations should be an attempt to create a storm at sea for the purpose of intercepting his voyage. The accusations against witches of America, in 1638 and 1657, the method of which is printed by the Spalding Club, the exercise of a power over the elements is one of the charges. In the curious narrative as to Margaret Barkley and others, preserved by Sir Walter Scott in 'Demonsology' (p. 318), we find the same condition. The specific superstition does not seem to have taken root in England, and Shakspeare, whose witchery in 'Macbeth' is essentially Scottish in character, has given it a place there—

*Though you walk the winds and let them fight Against the charmed night; though the fury waves Confound and swallow navigation up.*

It is a remarkable circumstance that nowhere are the

1978—9 R
identities between the opinions promulgated in doctrinal works and the practice of witchcraft more fully developed than in the confessions of the witches as produced in official documents. The horrible tortures, which the alarm produced by the supposed existence of a coalition with Satan seems to have prompted men of ordinary humanity to sanction, appear to have generally called from the exhausted victims an assent to whatever narrative was dictated by the devil and the impudence of those acquainted with the best authorities on the subject, would know how to connect the received doctrines of sorcery with whatever train of real circumstances may have been brought home to the victim. Knowing in fact the capacity of man and the artlessness of women, they would easily fill up the supernatural details. Margaret Barclay, tried in 1618, was, according to the record preserved by Sir Walter Scott, subjected to 'gentle torture.' Sir Walter calls this 'a strange contradiction,' saying it is not without precedent, and we can imagine it taken from Bensfeldus, who tells us of a lady who, in 1590, at Cologne was subjected to 'moderata torture.' The Inquibus and the Succeedus—the former the visitant of males, the latter of females—are prominent in the confessions, and opened a new era of psychological inquiry. According to the book 'De Spectris,' Soc. ab Hr. aforesaid, it is given as a characteristic of the confession of a female: 'Ex eo tempore Deo et religiis renunciasset, et illam [Diabolum] sic concussisset secum, ut veritas in alio agenti, nisi peritingum erat quidquid esset notabile. These notabilities, and singularly enough the last and most particular one, are enlarged upon in several of the Scottish trials. Reference may be made to the appendix to Pitcairn's 'Crimes Trials,' p. 430, and to a pamphlet called 'The Confession of Walter of Renfrew.' Until the cairn's of the above-mentioned case, the trials of the witch of Scotland goes over the same subject, and further curious matter will be found in Glanville, 'Saducismus Triumphantus,' Spener, 'Malleus Maleficarum,' p. 297; and Deirio, 'Disquisitiones Magicae,' p. 74. There is no doubt that some of the confessions recorded were voluntarily made; and that, whether dictated by their own imagination or by their reading, the self-accusers did not speak on the suggestion of others. There are thus two mingled elements in the confessions, the suggestion of which is necessary to and would materially aid a philosophical examination of the causes which have produced such singular effects: the one would bring before us the physical and psychological causes from which the mind voluntarily imaged itself an actor in a supernatural occurrence; the other would explain the utterance of confessions of such acts by persons who until they were subjected to torture never imagined their existence. The confessions made under torture were frequently revolved during mental and physical excitation; and the circumstance reminds one of the recantation in the old French case of the trial of Father Girard, whose victim Catherine Cadiciere confessed that she was the agent of a conspiracy against him; and of the recantation in the later case of the dam Madame Limet, who, in a state of excitation, as she maintained, of the recent occurrence of an atrocious murder, and of a harassing cross-examination in relation to it, confessed to having witnessed it under circumstances which blackened her previously-unblemished character, an admission which she afterwards revoked.

The influence on society of a belief in witchcraft was of the most pernicious kind. It gave an unchecked flow to all the malignant passions; some venting them in accusations to the witchcraft, others taking them in the death of their fellow citizens. In the year 1515 five hundred people are said to have been executed at Geneva on charges of witchcraft; and Remigius, the inquisitor, boasts that he put nine hundred to death in Lorraine. The first person who lifted his voice against these execrations was John Pits in 1568. He and his followers carried on a controversy with Delrio, Bodinus, Schranius, and others, in which it is generally admitted that the defenders of witchcraft were the more successful logicians. The supporters of the practice had the compact and complete system of sophistry, and he who would break through it must, like a Bacon or a Locke, possess strength enough to destroy the whole fabric. Wierus and his followers ventured to raise their voice against the conviction only of taking manifestation of the power of diabolical possession, not its existence. Against the brutal practice of burning a witch to see if she will sink or float, which may be traced as an ordeal succeeding that of the red-hot ploughshares, and which inferred that a body in which an evil spirit dwells is lighter than water, they could do no more than adduce the experimental fact that the herd of swine into which Jesus cast out the spirit, running into a lake, were drowned. Of all the opponents of this superstition the English Reginald Scot, who wrote in 1584, was perhaps the most successful in the employment of an acquaintance with natural operations, and the story of this spirit, found in a remarkable place, was the ready sarcasm. He was followed by Hasretel in 1598, and in 1729 by Francis Hutchinson, who however appeared chiefly to the unlearned, among whom alone the best understood the present superstition.

The learned men of Europe generally believed in witchcraft down to the end of the seventeenth century. Selden has an apology for the law against witches which shows a lurking belief. He says that if he believed there was a witch, it was not by force, but by the power of the law, that he could take away a man's life; 'this was a just law made by the state, that whoever should tell half thrice and cry "bus," with an intention to take a man's life, shall be put to death.' The logic of Selden if, unainted by knowledge of the witchcraft and superstition that in a work called 'The Institutes of the Law of Scotland,' published at Edinburgh in 1730, by William Fawter, an author deservedly neglected by practical lawyers, who, in a specific definition of the nature of witchcraft, then as now, stated the following: 'Witchcraft is a practice which, if there may be, and have been witches, and that perhaps such are now actually existing; which I intend, God willing, to clear in a larger work concerning the canon law. This promised work never made its appearance.'

WITCHCRAFT, or literally an assembly or gathering of people, from the Anglo-Saxon 'gemono,' an 'assembly,' and 'to know,' which has the same root, 'wit' or 'wise,' the words wit, witness, wise, and the legal phrase is to 'wit.'

Although the chief rulers of the Anglo-Saxon state nearly down to the time of the Conquest, bore the title of king, and in their charters and letters attached to it most of the honours and emoluments belonging to it, it never was a hereditary one to a person of the royal blood, but in the Barbarous nations, kings indulged, yet these little regarded in power over lesser chiefs of that nation, who either had themselves shared together with their own particular followers, or were descended from ancestors who had so shared the risk of the first invasion which seated the tribe in Britain. To election by the chief of the king, the legal term was first used;' and if the sceptre descended to his race, it was, if not by force of renewed election, certainly by means of the formal recognition of the new king by the nobles in an assembly convened for that purpose. If of the archbishops, bishops, and abbots, the judges (if such there were), and the largest landholders formed part. It was not upon the death of the last instance, that five hues of land were found to be an indispensable qualification. Whether the right of election was not a doubt; judging by the analogy of the silence notes, and of all the political and judicial institutions of our Anglo-Saxon ancestors, it is probable that each district appointed a chief, who assembled and received the person (if an active part in their deliberations) by means of his responsible officers, his twelve, and of the persons who did serve for it at the county court: there is however, we believe, evidence that there was a systematic representation of the people by enos, or men by persons elected for that specific purpose.

Nor did the functions of these national councils cease with the election of a king: their meetings, if not peculiar...
cal, were frequent, and were held usually at the great festivals of the year, Whitminiade, Christmas, and especially Easter; they formed the highest court of judicature in the kingdom; they were summoned by the king in the case of any political emergency; their concurrence is always mentioned in the (trials) of roads and bridges, (acts) of war and peace, necessary to their validity, as well probably as to that of royal grants and charters; and the chief persons who attended them frequently expressed their approbation of such royal acts by their signatures under that of the king. The function was to be filled in the dominions of one king, whether as breveta (whatever office that name implied), or by the union of smaller states into one kingdom, the national council retained its powers. It was called by the king, in his grants and laws, his witan, his wenage, his myrce, synod, archbishop, great latter, his eadgān (worthy); and in Latin by similar names, e.g. magnum concilium saponem, universae gentis Anglici consilium; or by names indicating the rank and property of the members, such as those of the members resisting the prelates, the chief barons, the council of the kingdom, the council of the county, the council of the shire, and the council of the hundred. The composition of this council must be gathered from the words in which its members are mentioned, and (as we have said) from its analogy to other smaller political assemblies.

Mr. Sharon Turner enumerates, from various extant charters, the designations given by the king to his great council in the preambles of those instruments, or added by the members themselves to their signatures; and says, in the words of the Progress, in the English Commonwealth, more fully sets forth the office of the proceedings of the great council (Proofs and Ills. p. cxxviii.). After the signatures, or more frequently crosses, are found the titles of Bishop, abbot, deacon, priest, prince, duke, comes, earl, baron, viscount, miles; and of the great household officers of the palace, pincerna, disc thegn, chief carver, &c. The names especially of ecclesiastics often have some verb after them, which is fantastically varied, as saulfi, comprovbavi, favi, losadavi, confirmavi, subscripti, to which the petty kings added, a great variety of subjects, less used, which self frequently adopted in his signature the form Confessio et signo crucis munis. To some charters the names or crosses of princesses of the royal family and of abbesses appear. In one case the title electus follows a name. One story belongs to the reign of Ethelwulf (825) relates to the church a tenth, with the assent of the kings, thanes, barons, and people. The eighth law of Edward the Confessor names the people; and the 32th law recites that it was composed by the common advice and assent of all bishops, priests, monks, nobles, and people; for it is the rule of the wise and elders, and of the people (populorum) of the whole kingdom. Sergt. Rulehead, in his preface to the Statutes, conjectures, at the same time his ignorance, that the scribe resembled our House of Commons, the electus of the House of Commons were members of the privy council. Undoubtedly some of the functions which in far more recent times the privy council has performed did devolve upon the witan; for instance, their approval was required for certain acts of the king; and generally their assent was deemed necessary to the validity of such acts, and was considered and to sanction those which were submitted to them.

In concursing in royal charters and grants the witenagemote performed the double office of consenting to and of promulgating royal acts, which was analogous to that of the shire-mote, which in those rude days distributed justice rather according to the notoriety of the facts than to any systematic rules of investigating the truth, and quelling itself the interest and loathed that the main transactions touching the rights and property of individuals within its district should pass in its presence.

In those cases where the administration of justice was intrusted to the witan, a jury of the whole district or of any particular portion of it, was appointed, which was analogous to that of the shire-mote, which in those rude days distributed justice rather according to the notoriety of the facts than to any systematic rules of investigating the truth, and quelling itself the interest and loathed that the main transactions touching the rights and property of individuals within its district should pass in its presence.

During the Anglo-Saxon times the possessions of the king, and the ordinary payments made to the crown by every landholder, together with the duties paid by townships, were sufficient for the ordinary wants of the government, especially as the triple duty (tribus necessitas) of repair, law, and bridge, maintaining the walls of the burgs (burh-bote), and resisting invasion (the fyrd), was invariable. The king too was entitled to tolls on goods sold in most markets and fairs, and to customs on imported goods; but in those emergencies when a pecuniary contribution by the man of the nation, the witan were called on to accede to the tax. If the domestic affairs of the nation were thus considered and confirmed by the witan, treaties with foreign states were equally submitted to their approval. Thus the treaty between Alfred and Guthrum the Danish leader, whereby the eastern counties were abandoned to the Danes, is made with the approbation of the witan.

The duties of the witenagemote were therefore partly legislative, partly, and indeed for the most part, judicial. In order what a political act was to be promulgated, or his own state, the court where the king's laws and his most important acts were promulgated, his rights ultimately enforced, and justice administered if denied elsewhere: and in enumerating the offices one is necessarily led to observe the analogy which subsists between that ancient aristocratic assembly and the House of Lords of recent times.

When the Norman Conquest had destroyed all the rights of the English people, alienated from their minds the memory of their institutions; and the king, as the emergency arose, availed himself of those institutions to strengthen his title or assist his projects; and on the other hand the Norman nobles found in them the means of uniting to themselves the good of the people, in order to check the oppression or to limit the power of the crown. The circumstances of the Norman invasion, and the fact that the nobles who accompanied William in that enterprise were rather fellow-adventurers than subjects, led him to establish himself and his successors of a general council of his chiefs, sometimes expressly to consult upon state affairs, often only for the avowed purpose of celebrating with him, and at his cost, the great religious festivals of the year. There to 'Conquête d'Angleterre,' took place, and is marked on the 'Chronique de Normandie,' that before William undertook the expedition to England, his immediate counsellors, whose concurrence he had obtained, warned him 'that he must also ask aid and counsel of the people generally,' that he who commanded the English nation was to be supreme himself, and that the duke then convened the principal chiefs, ecclesiastics, and merchants. Sir F. Palgrave observes, that the great council of William the Conqueror differed little from the witenagemote, and that the Saxons and Normans maintained it the same, and that all the races in the kingdom (at least those in Normandy) were mingled in it, and that the Conqueror gave it the form of a national council by the ancient name of witenagemote.

By degrees the English recovered some political rights; their Norman rulers yielded, at least in words, to their subjects and for the respect of their ancient institutions. The people called them, the laws of Edward the Confessor: the machinery already established of townships, hundreds, and shires, with their moots (assizes) and officers was maintained, as useful for the collection of the crown taxes as for the maintenance of law, order, and the protection of the life and property of individuals. Hence, although the ancient popular officer, the reeve, was displaced for the Norman count, viscount, and bailiff, who derived their authority immediately from the king, they had the name of shire-mote, and the habit of representation at that assembly of the burgs and hundreds in the county remained.

The power of the aristocratic element (unquestionably the main ingredient) in the witenagemote was therefore
never suspended, although in its conflicts with the crown it might be greater or less. Its influence was most effi-
ciently shown when, in 1215, the nobles wrested Magna
Charta from King John. The popular element in the wide-
nomenclature assumed a distinct form when, in the succeeding
reign (1265) Simon de Montfort, earl of Leicester, high-
Steward of the realm, issued in the king's name a writ to the
sheriffs of all counties, commanding them to return to
the parliament two knights for the county, and two burg-
ese of the borough, to consider concerning the affairs of
the nation. [PARLIAMENT.]

(Turner's History of the Anglo-Saxons; Sir F. Palgrave's Rise and Progress of the English Commonwealth.)

WITHAM. [Essex.]

WITHAMITE occurs crystallized. Primary form an
oblique rhombic prism; it is found also in small imbedded
globular masses composed of radiating crystals. Fracture
uneven, sometimes crude, sometimes glassy. Colour, red
and reddish-white. Streak white. Translucent; opaque.
Specific gravity 3-137.

It is not acted on by acids. Before the blowpipe intu-
mesces and fuses with difficulty into a dark-grey scoria.

With salt of phosphorus it dissolves with effervescence
into a globule which contains a little silice, and
becomes opaque on cooling.

Found at Glencoe in Scotland, and is regarded as a
variety of epidote. Coverdale's analysis performed on
only six grains—

104-53

WITHER, or WYTHPER sometimes improperly (Wither), GEORGE, was born 11th June, 1688, at Bentworth, near Alton in Hampshire, and was the son of George Wither of Bentworth, who was himself the second son (the first by a second wife) of John Wither, Esq. of Many-
downe, near Wotton-St.-Lawrence, in that county. The
name of Wither's mother was Anne Serle. After receiving the
usual instruction at the grammar-school of Colemore, or Colemore, under its eminent master, John Graevs, he
was sent about 1604 to Magdalen College, Oxford, where
he had for his tutor Dr. John Warner, afterwards bishop of
Rochester. After remaining however about three years,
during which time, according to his surviving biographer,
Anthony Wood, he 'made some proficiency, with much ado,
in academical learning,' he was called home without having
taken a degree, as he himself tells us (in his 'Memoir'
'written for the plaugh.' Wood only says that 'his gentry
being addicted to things more trivial' than the studies pursued at the university, he 'went to London, and entered himself first at one of the inns of
Chancery, afterwards at Lincoln's Inn.' But, 'continues
Wood,' he 'regarded in his youth things more smooth
and delightful, he did at length make himself known to
the world (after he had taken several rambles therein)
by certain specimens of poetry; which being dispersed in
several hands, [he] became shortly after a public author,
and much admired by some in that age for his quick ad-
vancement in that faculty.' Some pieces of less preten-
sion had already made his name known in a limited circle,
when in 1613 he published his volume of poetical satires
on the manners of the time, entitled 'Abuses Stript and
Washed.' This was the first thing in which he showed
goal to the government he was committed (it is not
stated by what authority) to the Marshalsea prison, and lay
there for several months. While in confinement he wrote
and published his 'Satire to the King,' 1614, in which he
complains of the indignities he had suffered during his
detention, and which is supposed to have procured his release. The
spirit of his poetry and the usage he had met with now
made him a great favourite with the puritanical party, by
which Wither was sometimes insinuated to have been
"crispe run for his general fuse pouring-forth of English rhyme." Afterwards, it is added, 'the vulgar sort of people' came to regard his
poetry as having in it something prophetic. He de-
nounced the abuses of the times, too, in various prose para-
ses as well as in his more frequent discharges of
flowing verse. All this while he appears to have lived in
easy circumstances on the landed property which he had
inherited. But, as might have been expected in so hot and
restless a spirit, Wither, as soon as the storm of the civil
war began to blow, hastened to throw himself into the
arms of that element of which his name was so well
known, without much minding which side or what prin-
ciples he fought for. He served as a captain of horse, and
was quarter-master-general of his regiment, in the expedi-
tion which Charles I. led against the Scotch Covenanters in
the spring of 1644. (Also, it was during this time that
he engaged in writing the 'Lamentations of the
Earl of Looe.' Years after, when the war began between the
kings and his English subject, Wither sold his estate and raised a troop of horse for
the Parliament, in whose army he was speedily promoted to
the rank of colonel. On his death-bed, in the year
1647, he is said to have uttered the motto, 'Pro Rege, Lege, Græge.' Being taken
prisoner by the royalists, he is said to have been indebted
for his life to a bon-mot of Sir John Denham.—Denham
memorial tablet in Westminster Abbey. In Wither's
works, after having got into his clutches, 'denial is not
made to hang him, because, so long as Wither lived, Sir
Denham, would not be accounted the worst poet in Eng-
lis.' He also probably soon recovered his liberty. Not
long after this, Wither, on the contrary, in the
Long Parliament a justice of peace in quorum for Hamp-
shire, Surrey, and Essex, which office he kept six
times, and afterwards was made by Oliver major-general of
all the horse and foot in the county of Surrey, in which em-
ployment he was so addicted to ticking his fingers that
he was said to have a great odium from the generous
royalists.' A MS note on a copy of one of his tracts in the British Museum, is
'Boni Ominis Votum,' printed in 1656, describes him as
lately made master of the statute office.

At the restoration Wither was only forced to
dezarte this spoil, but was by a vote of the Convention
Parliament sent to Newgate on the charge of being
the author of a publication entitled: 'Vox Vulgi,' which
was regarded as a scandalous and seditious libel. There
is a extract at large from this pamphlet, which is
entitled 'The Prisoner's Plea humbly offered in a Remo-
strate, with a Petition annexed, to the Commons in
parliament assembled, by G. Wither, falsely charged to
have composed a libel against the said Commons, and
therefore now a prisoner in Newgate.' Wood asserts that
he afterwards confessed himself the author of the
obnoxious publication, upon which he was convicted
of high treason, to the Tower, with orders that he should
be hanged, drawn and quartered. It is said that he
used the good use of pen on his situation, and at
some time an impeachment was ordered to be drawn up
against him. The impeachment does not appear to have
been proceeded with; and he even contrived, by the device of
the keeper, to write and to send to the press from time to
time circulars containing very valuable information. It
appears that he was a grandson of Wither's, Hunt Wither, of Fidding, in the
county of Southampton, designating himself colonel of
foot in her majesty's army, and brigadier-general in
the service of Charles III. of Spain, was alive in 1667, and that the
place to which he had been committed had been
transferred to the possession of an heir female, and was a few years ago
held by Mr. Bigg Wither, who in consequence had taken the
old family name. (See 'Memoir of Wither' in Bibliographi-
ca, vol. i. pp. 1-18, published in 1819.) Anthony
Wood, in hisdetach from his account of Wither with the critical remark that 'the things that he
had written and published are very many, accounted
for the multitude of scholars mere scribblers.' These works fill a number of volumes, the best edition of
the 'Fasti Oxonienses.' But the most detailed catalogue
of them is that contributed to the 'British Bibliographer'
by the late Mr. Thomas Park; it includes 112 articles (among
which however are some not known to have been
published and extant) under vol. i. pp. 173-300, and
110, and vol. ii. pp. 17-32, 379-391. Various bibliogra-
phical
Obsequies. A Satire to the King, Epithalamium, or Nuptial Poems, The Shepherd's Hunting, His Motto, and Hymns and Songs of the Church, &c., Svo., London, 1622. This reprint is without date, but was executed about 1820, by Gutch at Bristol, under the superintendence of the late Dr. Nets. It appears to have been intended as the commencement of a complete edition of Wither's poetry; but it was carried no further than the two first volumes, and the greater part of the impression was sold for want of paper.

The first edition, 1st and 2nd, fill the first volume, making 457 pp. 9. Another reprint of Selections, in 2 vols. Svo., also without date, and without any general title-page: vol. 1. contains * Fair Virtue, the Mistress of Philaretus,* 215 pp.; and *Selections from Abuses and Whipt,* the latter of the volume on p. 347, vol. ii. contains the first five cantos in full of 'Britain's Remembrancer,' and the metrical summaries of the 6th, 7th, and 8th; selections from a 'Collection of Emblems, Ancient and Modern,' London, 1694; and *Selections from Halmah, or Britain's Secretary.*

Wither's poetry is of very unequal excellence, and a good deal of it is worthless enough. His fatal facility, which grew upon him as he advanced in life, and soon debased his style from freedom to slovenliness, has left nearly all his work a mass of negligence or want of sense, or other. But there was in him a true poetical genius, a quick and teeming invention, a universal sympathy, a fancy that could gild any subject, or ' make a sunshine,' like Spenser's Ura. 'in the saddest place,' above all, a natural love of truth, and a contemptuous scorn of what may be sometimes wanting, has put a life and enduring freshness into all that he has written. His earliest style is his happiest; in that he seems to have sought by art and pains for the directness and transparency for which he afterwards turned to negligence or chance; but he also took, apparently from design, to a greater harshness both of phraseology and rhythm; but, both in his verse and in his prose, his English is rarely without the touch of great ease and clearness, as well as idiomatic vigour.

WITHERING, WILLIAM, was born in 1741, at Wellington in Shropshire, where his father was a surgeon-apothecary in considerable practice. He received his early education at a school kept by the vicar of his native village, and then commended his medical education under his father's instruction. After spending the usual preliminary time with his father, he was sent to complete his medical education at Edinburgh, in the university of which place he took his degree of Doctor of Medicine in 1766. He then proceeded to the practice of his profession at Stafford, where he married; but not succeeding, he removed to Birmingham in 1774. Here he became the successor to Dr. Small, and quickly succeeded in obtaining a large and lucrative practice. His income is said to have been between 2000l. and 3000l. per annum, and he had a large and profitable private practice in London. In the midst however of his great professional avocations he found time to cultivate with great ardour the sciences connected with natural history. He was exceedingly attached to botany, and having become acquainted with the botanical pursuits growing in Great Britain, he was induced to publish, in 1776, a work on the plants of this island. It appeared first at Birmingham, in 2 vols. Svo., and was entitled 'A botanical Arrangement of all the Vegetables naturally growing in Great Britain.' As it was the first, and first it was little more than a translation of the descriptions of the British genera and species from the great work of Linnaeus, with the addition of many of the habitats of the plants from Ray's works, and was therefore quickly and found a sale. A second edition was published in 1793, and a third in 1796. In this edition the work was increased in size to four volumes, and a vast amount of original matter added, so as to give it quite a different aspect to the reader from the first edition, in which he was much assisted by many of his botanical friends, and he has everywhere acknowledged how much he was indebted to Dr. Stokes and Meares, Woodward, Valley, Stackhouse, and others. Since the death of Dr. Withering several editions of his ' Arrangement of British Plants' have been published. It is now however entirely superseded by the more valuable manuals of Smith, Hooker, Lindley, and Babington. It had the merit of being the first British Flora arranged according to the Linnaean system; and the early editions may now be consulted with advantage on
the properties and uses of the plants native to Great Britain, and the traditions about them.

Botany was not Withering's only scientific pursuit; he was fond of chemistry and mineralogy. He published, in 1735, a translation of Bergmann's Microscopica Regni Mineralis, with the title 'Outlines of Mineralogy.' He was a fellow of the Royal Society, and published several papers on mineralogy and chemistry in the Philosophical Transactions, of which the following are the titles:—In the volume of 1737-8, 'Experiments on the different kinds of Marie found in Staffordshire;' in 1782, 'Analysis of the Toadstone of Derbyshire;' in 1784, 'Experiments on the Terra Ponderosa,' in 1788, 'An Analysis of a Hot Mineral-Spring in Portugal.' These papers display a very complete knowledge of the chemistry of the time. But while pursuing science he did not neglect his profession, and he published several papers on medical topics. In 1778 he published 'An Account of Scarlet Fever and Sore Throat, especially as it appeared at Birmingham in the year 1777, 8,' and in 1793, 'A New Account of the Foxglove and some of its medical uses; with practical remarks on the Dropsey and other diseases.'

Although he was not the first to recommend foxglove (digitalis) as a medicine, he must still be looked upon as the first physician who knew how to use it, and by his writings gave it the character as a powerful medicinal agent, which it has since ceased to retain.

Dr. Withering was always the subject of a weak state of health, and was frequently attacked with inflammation of the lungs. He had no much willed to induce him to try a change of air for the benefit of his health, and he accordingly spent the winter of that year in Lisbon. At the latter end of the year 1734 he again went to Lisbon, and returned the following year. His health was greatly improved by this change, and he re-established himself at Edgbaston. Hall to a place called the Larches, previously the residence of Dr. Priestley. Here in retirement he spent the remainder of his days, and died in November, 1793.

Withering was a man of considerable discernment and great perseverance. He was humane towards the poor, and mild and courteous in his manners. He was conscientious in the practice of his profession, and never prescribed what he knew to be false. He never considered that he had any right to make use of the properties of plants which did not belong to him. Although reserved in public, he was exceedingly open amongst those who knew him; and he left behind him a large circle of friends. (Gentleman's Magazine, vol. liii.)

Witheringia, an extensive genus of plants belonging to the natural order Solanaceae, named in honour of Dr. William Withering. It has the following characters:—calyx 4-5-cleft, uncrenately campanulate; corolla rotate; tube short, limb 4-5-cleft; stamens 4 or 5, with connivent anthers; ovary elongated, style long, stigmas subulate, berry 2-celled, supported by the permanent calyx, many-seeded; the placenta adnate. The species of this genus are trees, shrubs, or herbs, with a soft wood, having a large pith, and the habit of the plants belonging to the genus Solanum. They are found in the Andes, and are all inhabitants of South America. About twenty species have been described. They are not handsome plants, so that they have not been introduced into gardens and hothouses. Their properties are not known, and similar to those of the family to which they belong. The first species of this genus, which was described by M. L'Heritier, is the W. Solanaceae. It has an herbaceous stem, and a root composed of fusiform tubers; the leaves are oval-oblong or obovate, or lanceolate, rather plicate; and the umbels are axillary, sessile, and longer than the petioles. It is a native of South America, and has very much the appearance of a Solanum. W. stramonifolia, a native of Mexico, is a tree, and attains a height of 10 or 20 feet. W. rhomboides is found on the Andes at a great height, and is a climbing shrub. In their cultivation the species of Witheringia require the same treatment as Solanum.

Withered, [Brit.], Wittebrechts, Wittebrechts, Wittof, Johann Philipp Lorenz, a German physiologist who distinguished himself as a writer of didactic poetry, was the son of Johann Hildebrand Witsch, professor of history, eloquence, and Greek literature, and was born at Duisburg on the Rhine, June 1st, 1725. In 1740 he entered the university of his native place, where, for the first three years, he warped himself to classical literature, history, and antiquities, and afterwards to medicine. His father then sent him to Utrecht and Leyden, on returning from which seats of study he obtained his medical degree in 1756, and practised first for several years. As the same time he was made corresponding member of the Göttingen Scientific Society, and also of the Royal Society. He continued at Ham and until received an offer from the university of his native place, in 1770, and living there in the midst of the German and Greek literature, which he held at the time of his death, July 3, 1789.

Though most of his poems had been composed before, but being, in fact, the productions of his youth, he did not allow himself to be thus and actively engaged in medical practice till 1782 that he gave them to the public, in two volumes, under the title of—'Academische Gedichte,' one, as Exeter observes, not particularly well chosen, since it does not convey any idea of his ability, but would have been of great service for his medical purposes. Witsch was a person of very considerable public spirit, since it is the philosophical sage, the man of thought, and extensive learning which is best suited for academic purposes. The Academy was well suited to the poetical spirit, but in the same degree to have affected rather than to have endeavoured to do. Still those who can overlook imperfections of that kind, and who have any wish to attain any, will not perhaps be thus and to some damage, but are capable of regrettable, and will be repaid by his 'Die Moralischen Ketzer,' and 'Sinnliche Erzählungen,' for the studious person which they require.
the first year of his reign, 772. His first campaign was successful. He penetrated into the country of the Engerns, took their fortress of Erkuburg (now Stadtburg, on the Dünewell) by surprise, and destroyed the town of the same name, a national monument. Great wealth was found there by the Franks. In the neighbourhood of this monument Charlemagne made a truce with the Saxons, and returned to his dominions in order to prepare his expedition against Desdivendis and the parochial churls. The battle of Grunburg, Charlemagne in Italy the Saxons prepared for a fresh war, and chose two commanders-in-chief, Witikind and Albion.

Witikind had extensive estates in Engern and Westphalia, and it appears that he was 'duke' of the warriors of these two provinces; and among his followers were Witikind and North Albingians. Witikind immediately invaded the Frankish territory; but in 775 Charles approached with a mighty host, and penetrated as far as the Oker, in the heart of the duky of Bremen. After several defeats the Eastfrisians and the Engern, whose duke was then Bruno, made peace and gave hostages to Charles. Bruno and Hessi were probably subordinate dukes. The Westphalians followed their example at Bocholt, where Charles made new progress, and built castles, in which he placed garrisons. In 777 he held a meeting at Peraden, which was attended by a great number of Saxons nobles and commons. Charles renewed the direction to which the Saxons were to pay tribute. Witikind however did not appear, but fled to Siegfried, king of Denmark, whose sister Gera he had married. Charles, believing that Saxony would keep quiet, turned his armies towards the Arabs in Spain; but no sooner was Bocholt abandoned than the Saxons under Frankish knights, renewed the war, and when the Saxons heard that a Frankish army had been destroyed by the Basques in the valley of Roncevalles, the whole country took up arms, and Witikind ravaged the Frankish territory as far as Cologne and Remagen. In Charlemagne's absence of Charles, against whom he secretly excelled the Sciri, a Slavonian nation on the right bank of the Elbe. Suddenly he crossed the Elbe and destroyed a Frankish army at Santnolnburg, that Witikind, intrusted, appeared with fresh troops, and having succeeded a portion of the Saxons to give up their principal leaders with their adherents, he ordered them all to be beheaded near Verden, in the Aller, 4500 in number (783). This victory was as great as that on the Saxons.

A bloody but inoffensive battle was fought near the place where Varus perished with three Roman legions, in the Reutuburg Wald; nor could Charles boast of having defeated his enemy in a second engagement which was occasioned by the source of the Hedebrun.

The places where Charles and Witikind had ranged their armies, two sand-plains, at a short distance from each, near Werdin, in a barren desolate country, are called to the present day, the one the Kersfeld, the other the Wittefeld. During the following year, Charles continued an obstinate struggle with the Saxons; and seeing the impossibility of subduing them unless he gained their chiefs, he sent messengers to Witikind and Albion, who remained in their possessions, more willing to enjoy the enjoyment of all their estates if they would adopt the Christian religion and recognize Charles as their master. Upon his proposition they both sacrificed the interest of their country to their own. They went to Attinicum, now bittern in Lorraine, where Charles, or his brother Hincmar, was invested, submitted to the Frankish king, and were baptized; thereupon they returned to their dominions (A.D. 785).

The final subjugation of the Saxons, which was not completely effected till the year 803, and the conditions of the peace, have been given in the history of the Teutonic nations. A proof of Witikind's attachment to the Christian religion is his foundation of the convent, afterwards chapter of St. Alexander, at Wildeshausen, in the grand-duchy of Hessenburg. In the respective documents (though in some of them only Witikind's name is inserted), submitted, there are some ruins, situated on a hill surrounded by the Rhine, which are said to be the remains of the chief residence of Witikind; and in the mountains near Dissen, east of Osnabruck, there is a ruined stronghold called Witikinds-Burg. It is said, but it cannot be proved, that Witikind was the first Duke of Osnabruck, a dukedom, in a battle with Geraldo, duke of Saxony. His body was interred at Paderborn, whence it was carried to Engern, and subsequently to Herford, near Minden. In 1377 the emperor Charles IV. ordered a monument to be erected to his memory in the cathedral of the chief Saxony. The stones which were carried from Herford to Engern, and deposited under that monument. (Conversations Lexic.) There is little doubt that a considerable portion of Witikind's hereditary estates were situated in the present duky of Olden.) Charles, the German princes who claim a descent from the Saxon chief, the house of Holstein-Oldenburg seems to have the best historical title.

(Eginhardus, Vita Caroli Magni, ed. Schminck, with the notes of Bessel, Bolland, and Goldast; Poeta Saxo (Anonymus) in Lebenh. Scriptores Rer. Brunen. ; Missor, Osnabruckische Geschichte, vol. i., the best work on the subject.)

WITNESS, from the Saxon witan, 'to know.' In the annals the witan is called in the record and testimony and of the competency of witnesses are so fully discussed as to render needless any further notice of them, if a recent Act, 6 and 7 Victoria, c. 83 (1843), had not made some important alterations in the law. These alterations are in the second part of the Act, regarding the courts of law in the courts have of late years inclined; they remove from the judicial inquiry after truth many of the obstructions arising from incapacity created by the law, and enable the tribunal to obtain all possible information, laying down the act. The witness and the witnesses adduced, and on the truth of their testimony.

This statute enacts that every one, excepting a party named in the record or the wife of such party, shall be competent to give his testimony in any legal proceeding, competent to give his testimony in any legal proceeding. This general rule is subject to the condition that he may have an interest direct or indirect in the matter at issue; and that no one shall be rendered incompetent to be a witness because he has been previously convicted of some crime. The act further enforces a party to a suit in an action to examine a defendant in the suit notwithstanding his interest.

The only exceptions made by the act are in the case of wills, which a party beneficially interested under them is still incompetent to prove, and in the case of actions of ejectment and of replevin. In the first of these actions, the interest of the plaintiff or tenant of the premises in question, and in actions of replevin the landlord of the defendant may be the real party to the action, though his name does not appear in the record. Therefore all the parties above are competent, and of these parties and of their wives is excluded.

WITNEY. [Oxfordshire.]

WITT, DE, JOHN and CORNELIUS, two of the ablest and most honourable of Dutch statesmen, were so inseparable in their career that the histories of the two are inseparable. Cornelius was one of those rare and invaluable natures who intuitively feel themselves born to perform a secondary part, and are probably, in the persevering unostentatious discharge of duties, more useful than even leaders of commanding talent. There is something extremely beautiful in the uninterrupted co-operation of two men like Cornelius and John de Witt, each among the very finest specimens of his own class of characters, and yet in the tie of brotherhood strengthens the bands of friendship.

The father of John and Cornelius was a leader in the party opposed to the assumptions of the House of Orange, and a member of the States General of Holland and West Friesland. He was of the line of the Orange family, a house of sufficient consequence to be included among the eight citizens imprisoned in the castle of Lüwenstein, in 1650. The young De Witts therefore were early imbued with hostility to the pretensions of the family of Orange, and devotion to the Republic; and at the same time encouraged by the position of their father, and was appointed as the leader of the party that should look forward to the immediate employment.
John de Witt was born at Dordrecht in 1625, and educated at Leyden, where, in addition to the studies necessary for one who aspired to rise in the state, he is understood to have cultivated the mathematical sciences with success. A treatise published at Leyden, in 1650, under the title "Elementa Linearum Curvarum," is attributed to him.

The death of William II, prince of Orange, on the 2nd of October, 1650, threw the management of affairs into the hands of the party to which De Witt's father belonged. Constitutional, honest men, having seen his talent, in the more particular notice of his career in the sequel of this article, appointed burgomaster of Dordrecht, the family influence obtained for John the office of pensionary of that city. The ability which he displayed in that charge procured for him, two years later (in 1652), when only in his 27th year, the more important appointment of grand pensionary of Holland, which he retained till 1672. During the intervening twenty years, he was, under the modest title of grand pensionary, virtual chief-magistrate of the republic. The period was critical one for Holland—during the earlier part of it De Witt was called upon to make head against Cromwell, and during the latter against Louis XIV., and he struggled at the same time against the inveracity of domestic faction.

De Witt, assuming the reigns government found the republic engaged in a war with England. A series of sea-engagements in which, although great skill and bravery were displayed by the Dutch and English commanders, and much victory, victory alternately had on each side without declaring very decidedly for either, paved the way for a peace which was negotiated by De Witt, and signed at Westminster on the 19th of April, 1654. On the part of the Dutch the honours claimed by the English for the victory in the Channel were conceded. A secret article was appended to the treaty, in which it was stipulated that the Stuart family should receive no support from the United States, and that no prince of the House of Orange, so nearly allied to the Stuarts, should be elected stadtholder of the Lower Provinces. The secret treaty was signed by the representative of Holland alone; the other provinces were as jealous of the ascendency of Holland as the republican party of the ambition of the House of Orange. This treaty embraced the great outlines of the policy in which De Witt persevered throughout the whole of his future administration:—Avoiding giving umbrage to the States of Europe by sticking on points of empty etiquette; aiming to preserve peace and the security of its foreign possessions for Holland; balancing the different European powers against each other; and guaranteeing Holland's independence in the House of Orange.

Towards the attainment of the last-mentioned object De Witt laboured indefatigably. The republican party persevered in Holland, but the Orange party triumphed in the Netherlands. The other states hesitated between their fears of being dominated over by Holland or by the prince of Orange. It was not till the year 1667 that De Witt obtained the assent of the States General to the perpetual edict, by which the office of stadtholder was declared to be for ever abolished. There was however no admixture of personal hostility to the prince of Orange in this persevering zeal for the destruction of his house's power. William, prince of Orange, (afterwards William II. of England) was towards him child, and thus the hatred against De Witt which his mother endeavoured to instil into him by flattering his own ambition, which rendered him ready enough to take advantage of the grand pensionary's unpopularity, always retained and expressed, in his guarded manner, a grateful and respectful sense of favour in which De Witt behaved towards him during his minority.

The next care of De Witt was to introduce order into the finances of the republic. In this he succeeded so well that the States of Holland presented a formal request to him that he would develop his financial system in writing.

Mutual respect had established a friendship that might almost be termed confidential between Viscont Turenne and De Witt. Turenne, in 1660, had endeavoured to persuade the French government to conclude treaties with Portugal and the United Provinces, as a check upon the ambition of Spain, but had been thwarted by Maximilian. On the death of that minister the viscount renewed his representations to Louis XIV., who left the affair entirely in his hands. The price at which Turenne obtained the signature of the treaty of commerce between France and the United Provinces, concluded in 1661, by which each state conceded to the other the entire freedom of commerce in their respective ports, and the States General guaranteed the possession of the Dutch West India Company's establishment to the Dutch, was guaranteed to the Dutch the right which they claimed of fishing off the coast of Great Britain and Ireland. The British cabinet made a feeble remonstrance against this last article, but Louis contrived to appease them for the time.

But the afront rankled in the public mind of England, and the commercial rivalry between that nation and Holland soon accumulated other grounds of complaint. The mariners and traders of the two countries had frequent quarrels on the coast of Africa and in the Indies, and persisted in representing the other as the aggressor. War was declared between Holland and England in 1665. De Witt invoked the aid of France, but in vain: Louis XIV. only pressed his rival by the intervention of his two brothers, the Duke of York and Prince Rupert of Hesse, who forced to seek shelter with the remnant of his fleet in the Texel. On this occasion De Witt gave a striking instance of the daring self-confidence which a great enterprise on land and sea alternately in his possession of the republic where the fleet could be refitted. The pilots refused to take upon them the responsibility of navigating the ships from the Texel to Antwerp, by a course which would secure them from the attack of the English fleet. But De Witt insisted, and his fleet was at last safely conveyed to the Shallows. De Witt repaired on board the fleet, took the responsibility from which skilled professional men shrank; conveyed the fleet in safety to Antwerp, where, under his energetic superintendence, it again took the sea in fighting trim. The squadron was at first defeated, but soon declared in favour of Holland, and ostentatiously offered orders to his fleet to join that of the United Provinces. No junction however took place, and after two more well-contested battles between the naval forces of Holland and France, peace was signed, by which France and Denmark became parties, in 1667, to the treaty in which Denmark and France became parties, between the belligerents, on the 30th of July, 1667.

De Witt endeavoured after the peace to concentrate his attention upon the internal organisation of the republic. The efforts against the establishment of the edict that allowed to be the first fruits of this determination. But the conduct of the French king soon interrupted these labours by drawing his attention to foreign affairs. Louis XIV. was determined to recover the Spanish Netherlands, and to degrade the States General, in view that they fell by right to his queen on the death of her father the king of Spain. Turenne took one fortification after another with his usual rapidity, and was advancing towards Brussels, when the marquis de Rodigo represented to the States General, that if France were allowed to conquer the Netherlands there would remain no barrier between it and the United Provinces. These representations were backed by those of Tempel sent by the English ministry to propose an alliance between the two powers, and a view to oblige France and Spain to conclude a peace. This assurance coincided with the policy of De Witt, who felt the danger of irritating France, and the equal danger of remaining passive witness of its aggression. Peace was signed on the 7th of February, and ratified on the 26th of April. At the same time the forces of the republic were successively augmented by De Witt: 30,000 infantry were raised, and quartered in the Indies, and four large ships put in commission. These negotiations were accelerated by the progress of the French arms in Fance Comité. The treaty disposed France to follow the overtures of peace, as the invasion of France. The court of Spain, on the other hand, would not refer the case to the court of Spain; and under the influence of De Witt and Temple the peace of Aix-la-Chapelle was signed on the 2nd of May, 1667. Louis assembled his anger at the part taken by the United Provinces in these negotiations till an opportunity of avenging himself should offer. In 1670 Charles II. was persuaded by the intrigue of
the French court to promise that England would withdraw from the Triple Alliance. In 1671 the bishop of Münster and several Roman Catholic princes of the Empire entered into a league with France for the purpose of reconquering some frontier towns which they alleged had been unjustly and forcibly taken from them by Sweden. In November, the council of regency appointed to conduct the affairs of state during the minority of Charles XI. was also detached from the interests of Holland. The inaction of De Witt which now appeared to the mob as insufficiency to prevent the bodies would appear accountable but for two circumstances which contributed to paralyse him. The first was the anarchical constitution of the republic, in which there was no central authority, every province and almost every town being a more or less independent state. The consent of an immense number of petty councils was necessary, composed of men whom immediate and visible danger alone could convince of the necessity of making the slightest sacrifices. The other circumstance was the great strength of the Orange party, to which a large portion of the members contributed: popular fickleness, tired of an administration of twenty years' standing; the number of disappointed candidates for office which had accumulated in the course of twenty years; the ineradicable malevolence of the Calvinistic class; and, lastly, the natural tendency of men to favour the pretensions of a house of real historical greatness. To this combination of adverse influences must the fact be ascribed which the event of the day has determined. The army was simultaneously assailed by the forces of Louis XIV. and the German princes, in the spring of 1672, the forts were held by garrisons weak alike in numbers and in the experience and want of discipline of the raw levies which composed them.

The partisans of the House of Orange seized the opportunity of national alarm and confusion to clamour for the repeal of the perpetual edict. De Witt and his friends were still strong enough to refuse this demand, but not to prevent the choice of Prince Orange by the States General, and the appointment of a new provincial council. 

On the 23rd of June, 1673, he is said to have served several years in the fleet of the United Provinces in his early youth. His later career however was essentially that of a civilian. On the overthrow of the Orange party in 1660 he was appointed administrator of his native town and elected deputy to the States of Holland and West Friesland. Soon after he was chosen inspector of dykes in the district of Putten. Ostensibly he held no higher office during the greater part of his brother's administration; but the confidence which his firmness, probity, business talent, and sound sense acquired from all rendered him in reality the most efficient supporter of his brother's power. As has been mentioned in the preceding sketch, he held a prominent position in the fleet during the years 1672; and in 1667 he had filled a similar post. On both occasions he distinguished himself by his bravery in action. After the battle of Solebay he was obliged to leave the fleet by a violent malady, and retired to Doorninck. Before his arrival the other magistrates had signed the re-vocation of the perpetual edict. A tumultuous crowd intruded itself into his sick room, demanding his signature to the document. With great difficulty his friends persuaded him to comply; but he added the initials V. C. (vocantur) to his name, and refusing to erase them, the mob was only pacified by one of his attendants doing it unknown to him. He was soon after arrested on a false accusation of conspiring to poison the prince of Orange, and was banished from the province. There, however, the mob resisted his command, and after the death of the rack he is said to have repeated Horace's ode, which begins, 'Justum et tenacem propositi virum.' On the 24th of July he was condemned to perpetual exile, and his subsequent fate has already been narrated.

On the 3rd of August, in the life of Cornelius de Witt are the same mentioned above in the sketch of his brother's career. Some valuable materials are also to be found for the history of both brothers in the works of Sir William Temple and the other historians of the time.
many cartoons to be worked in tapestry. He was afterward invited, while in Italy, by the elector of Bavaria, to go to Munich, and enter his service, which he did, and he remained there many years, until his death in 1628, and all works of art produced in his time were executed under his direction. He painted, under the arcade of the long gallery of the Hof-garten at Munich, a series of frescoes representing the deeds of Otto of Wittelsbach, and the departure of the emperor Ludwig IV. for Rome in 1327. The paintings were whitewashed over; the designs however are preserved in the tapestries which were worked from his designs in the engraving which were made by Amling from the tapestries; the prints are marked with the name of Pietro Candido as the painter. Amling engraved thirteen plates from these tapestries, representing the histories of the emperors Otto, Louis of Bavaria, and Otto of Wittelsbach, according to Huter, (Van Mander; Heinichen; Huber; Fiorillo; Dillia, Catalogue of the Gallery of Schlesischein.)

WITTELBACHIA, the name of a genus of plants belonging to the natural order Torontiflorae. The two species referred to this genus are now placed with Cochlospermum, which has the following characters:—the calyx of 5 permanent oval-oblong, blunt, unequal, imbricate sepals, the two outer ones of which are smallest, the whole becoming at length reflexed; the petals are 5, permanent, somewhat resembling the calyx in the aspect, unequal, and twisted in the bud; the stamens are numerous, having smooth filiform filaments, and linear 4-celled 4-sided anthers, which are fixed at the base, and open by a single pore at the apex; the style is biseriate, somewhat hooked at the top; the capsules surrounded by the permanent calyx, petals, and stamens, with, from 3 to 5 cells, and the same number of valves; the seeds are numerous and covered with wool, and contain a fleshly albumen, in which lies a siccus, in the cavity of which are the radicles pointing towards the hilum. The species of Cochlospermum are magnificent trees. They have lobed leaves with pointed petioles, and large yellow flowers arranged in panicles.

C. goyazum has 5-lobed entire leaves, which are borne on the thorny branches, and large yellow flowers. Saxony is a native of the East Indies, where it attains a height of 50 feet. It is the Bombax goyazum of Linnaeus. The C. ornitocense has smooth 5-7-lobed leaves, is a native of New Spain, and attains a height of about 20 feet.

C. instigus, the Wittebergia is the instigus of Martius, has conicaceous leaves palmately 5-lobed, the lobes coarsely, sharply, and doubly serrated. This tree is about thirty feet in height, and is a native of Minas Novas and Minas Geraes, Brazil. It is known by the name of Bauhin Caruru, and a decoction of its roots is used as a remedy for internal pain. It is also given internally in cases of accidents, and as a means of resolving abscesses. The remaining species of Cochlospermum is the Wittelsbachia of Martius. It has smooth leaves, in form like those of the vine.

All the species are handsome trees. They will grow in a soil composed of loam and peat, and may be propagated by cuttings, which should be placed under a hand-glass in a moist heat, or they may be raised from seed.

WITTENBERG, a town in the government of Meiserburg, in the Prussian province of Saxony, situated on a level sandy spot on the banks of the Elbe, over which there is a wooden bridge 1000 feet long and 25 feet wide, in the Prussian province of Saxony. The town is a fortified town, and has three gates. It was formerly a place of great strength, but in 1790 it was besieged by the Imperial army, and bombarded from the 10th to the 14th of October, by which the Prussian governor, Colonel Salvesen, was killed. It was captured in the siege, and 18 public buildings and 101 houses were destroyed. The works were then suffered to fall into decay, but as it had still a rampart and moat, it was fortified in 1813, as well as the other towns that would allow it. By command of Napoleon, on the advance of the Russians. It was subsequently besieged by the Prussians, who, as the French general Lapripye refused to surrender, took it by storm, in January, 1814. In this siege 299 houses were either burnt or pulled down. In the 15th and 16th centuries Wittenberg was the capital of the electoral circle of Saxony and the residence of the court. The University, one of the oldest in Germany, was founded in 1502, by the elector Frederic the Wise, by whom it was very amply endowed. In 1508 Luther was appointed Professor of Philosophy in the university, and, on the 31st October, 1517, he posted his famous Ninety-five Theses on the doors of the castle church of St. Mary's. He was thereupon created professor of theology, and was allowed the right to teach in the university. He was at this time a young man, 29 years of age, and had already celebrated 95 theses or propositions against indulgences. The tombs of Luther and Melanchthon, and of the electors Frederick the Wise and John the Constant, and the portraits of Frederick the Wise and of Melanchthon, by Cranach, were placed in this church. It suffered greatly in the years 1760 and 1814, but was restored in 1819, at the expense of the king of Prussia. Of the other four churches the most interesting is that which contains the tomb of Leopold I., father of Leopold II., King of Hungary, and which in which there is a celebrated picture, by Cranach, of the Last Supper. The town-hall likewise contains some paintings by the same eminent master. On the celebration of the third centenary of the Reformation, in 1817, the king of Prussia laid the first stone of a monument in honor of Luther. This monument stands in the market-place, and consists of a colossal bronze statue of Luther from a model by Schadow, on a pedestal seven feet and a half high, resting on a block of granite weighing 26 tons. About its base is the figure of the king in the guise of the Roman Emperor, and the following inscription:—

Die Wurzeln des preussischen Staates; Rodenius, Franz-Sources pour l'Estinction: Haeckel, Die Pflanzen Monarchie.

WITTENSTEIN is the name of a noble German family, which is probably descended from one of the Frankish nobles upon whom Charlemagne conferred extensive fiefs in the Duchy of Saxony. The name of Sayn-Wittgenstein, although it never possessed the county of Sayn. The former county of Wittgenstein was situated in the southern corner of Westphalia, and the sources of the Sieg and the Lahn, a mountainous river large, have a considerable number of woollen-cloth and linen, breweries, distilleries, and dyeworks. They likewise cultivate extensive gardens, and derive considerable profit from the Elbe fishery.

(Müller, Wörterbuch des Preussischen Staates; Rodenius, Franz-Sources pour l'Estinction: Haeckel, Die Pflanzen Monarchie.)

WITTENSTEIN is the name of a noble German family, which is probably descended from one of the Frankish nobles upon whom Charlemagne conferred extensive fiefs in the Duchy of Saxony. to the coalition (August, 1813). Prince Schwarzenberg was invested with the command-in-chief of the united forces of the allies, and Wittgenstein was superseded in his command by Barclay de Tolly for the Russian forces, and by Blücher for the Prussian army. He nevertheless continued in command of a strong division of the Prussian army, and in the battle of Leipsig (16th-18th October, 1813) he was at the head of 70,000 men, with whom he occupied the position round the villages of Mark-Kleeburg, Wachau, and Liebertwolkwitz. In the campaign of 1814, in France, Wittgenstein, in command of his old division, played some considerable part in the neighbourhood of Paris, but Napoleon defeated him in the battles of Marmont and Nangis. After the war with Napoleon was terminated by the two peacec of Paris, Alexander rewarded him with extensive estates in Po- dolic, and in 1822 he became governor of a city which he named Mutius. Wittgenstein became very infirmities, but this was derived from his commands during the war in France. In 1832, he was laid up with a severe illness, but the war in France was decided for good. In 1833, he became the command-in-chief against the Turks. The first campaign resulted in the capture of the Pruth and the Danube, and the conquest of Brulla, Isaksha, Varna, and other fortes, by which the war was decided. The war, however, was balanced by severe losses, and generally the result of the campaign did not satisfy the Tsars' expectations of the Russian officers, who would have preferred a bold and enterprising general to a leader of tactics, large and skilled in war, who were less the result of age than of fatigue. Wittgenstein was recalled on the 18th of February, 1829, but the emperor did not dismiss him without giving him new proofs of his esteem and generosity. Wittgenstein retired to his estate in July, 1831, and died in the beginning of the summer of 1843. In 1834 the king of Prussia conferred upon him and his successors the title of prince. The different histories of the war with Napoleon give a full account of the man who was to be subject to criticism, of whom Volume II of Oebel's Geschicht der Feldzüge Saches, 3rd edition, 1841, Von Plotho, Der Krieg in Deutschland und Frankreich in 1813 and 1814, 4 vols. 1819.

Conversations-Lexicon der Gegenwart.

EDRICH VON TROMLITZ, better known as a writer by his literary pseudonym of Von Tromlitz, the name of his father's estate near Weimar, where he was born on March 17, 1772. At the age of nine years, he was enrolled among the pages of the court of Weimar, and was allowed to prepare the court garden; having entered very early into the Prussian service he obtained advancement in it, and distinguished himself in the Rhine campaigns of 1792-95. It was about the same time that he made his first literary attempt, being evinced to the greatest advantage. The first book that appeared under the name of Jurgen von der Deutschen am Rhine, the author of which lived only to finish the first volume; and he also wrote several political pamphlets, at that period, and his romance Das Stille Thal. Though Schwilling had himself chiefly by his literary talent, that production was his last, until about twenty years afterwards, when he again appeared as a writer.

During that interval he was constantly engaged in military service, of which he recorded a great deal in various campaigns;—was at the battle of Jena; was taken prisoner at Premisau; became a commander of infantry in the army of the grand-duke of Berg (Murat); had a regiment in the Peninsular war, in 1811, when he was passed to the black regiment of foot, and in 1815 to the French; and in 1819 became a colonel in the Russian service. At the general peace his military career terminated, and he retired to Beuchlitz near Halle, where he followed farming for about the next seven years, and then went to Engtelein, where he made literary operations. He did not however remain at Berlin many years, but in 1826 removed to Dresden, in which city and in the neighbourhood he continued to reside till his death, July 28, 1839.

The name of Tromlitz was both a fertile writer and a favourite one with the public, is tolerably evident from three editions of his collected tales and novels;—two in 36, the last in 27 volumes—having passed through the press between 1833 and 1840. He distinguished himself chiefly by his historical romances—a species of literature greatly in vogue, and in which he took Scott for his model, and with perhaps as much success as any other of his imitators. Interest of story, cleverness of invention, and an agreeable style of narrative, sufficiently recommended his productions of that class to readers in general, though it has been alleged that they show no very great knowledge or deep insight into human nature. Those of most note among them are:—Die Pappenheimer, Frantz von Sickingen, Mutius Sforza, Das Leben des Markgrafen Albrecht von Brandenburg, and Die Carreras. He also made a strong attempt at the drama in his Don Quixote (1836), but not with such success as to encourage him to pursue that career.

W. U. VIVELISCOMBE.

WOAD (Isatis tinctoria) is a plant which was once cultivated in Britain to a great extent for the blue dye extracted from it. It has been greatly superseded by indigo, which gives a stronger and finer blue; but on some soils it might be still cultivated to great advantage, especially as it is said to improve the quality and colour of indigo when mixed with it in a certain proportion.

The woad is a plant of the natural order of the Cruciferae, and derived from the mustard family. It is a strong tap-root, which lasts two years. The height of the plant when in perfection is from three to four feet. It throws out many branches from the upper part of the stem. The leaves are alternate and smooth, the lower on foot-stalks, the upper ones sessile, long and arrow-shaped. The flowers are yellow, in panicles at the extremity of the branches. The fruit is a heart-shaped pod, with two valves containing one seed only. It grows well on the borders of the Baltic, and is very hardy.

It is still cultivated to a considerable extent in the south of France and Flanders. It requires a good substantial soil of considerable depth and fertility; for the larger and more numerous the leaves are, the more profit is derived from the plant. The clay or loam is not so good for its growth, nor a loose sandy one. The first would prevent its roots striking sufficiently deep in search of nourishment, and the latter would be too loose, and not keep up a sufficient degree of moisture.

When it was largely cultivated in England, old pastures ploughed up afforded the best soil for the woad to grow in. These were often taken at a very high rent for two years by men who made it their business to cultivate the woad, and who found no profit in its cultivation. In consequence of this practice some proprietors prohibited their tenants from cultivating woad, a short-sighted policy equally injurious to both. To have good woad the land should be naturally very rich, or much manured beforehand; and the leaves should be gathered when not ripe, but just beginning to ripen. Nothing but completely decomposed dung should be used, or compost made on purpose a long time before.

The land, having been prepared by repeated ploughings and perfectly clear of hayfields, should be kept very close with a depth of six inches. On these beds the seed is sown in February or very early in March. It is sometimes sown broadcast, and the plants thinned out, but sowing it in drills, two rows on a four-feet bed, is much the best practice. The drills are one foot from the edge, with two feet clear between them; some make five-feet beds, and there is an interval of thirty inches between the rows, which allows of better cleaning, and gives the plants more room to spread. When the plants are come up in the rows, they must be thinned by hand, leaving, when the leaves are about three inches long, two leaves only to each plant; the leaves will soon fill up the intervals. They begin to ripen in June. They are fit to gather when they begin to droop and become yellowish. This should be done in very dry weather, and after the leaves have either twisted off close to the stems or cut down with a sickle. Great care must be taken that no dirt or earth adheres to them. Some recommend taking off the lower leaves first, when they appear ripe by drooping and turning yellow, and letting the upper ones remain until they have given up appearance; then nothing but ripe leaves will be gathered. This stripping may be repeated two or three times as the leaves grow again. The plants destined for seed are only stripped once or twice, for fear of weakening them, but probably be advanced two or three years from them at all, but to leave the whole strength for the formation of 3. 3. 2.
seed, which will be larger, and produce finer plants the next year.

The gathering of the leaves is the best; they should therefore be kept separate to obtain the best dye. As soon as the leaves are gathered, the breads should be well and deeply hoed or dug, to give a fresh impulse to the roots. The leaves are naturally full of sap, and soon begin to decay if not laid in a heap. They should therefore be partially dried, and immediately carried to the mill to be manufactured.

There is a variety of this plant cultivated in Flanders and about Valenciennes, which has seeds of a violet colour, and from which it is larger than the other, and gives a better dye. It is that which is cultivated near Avignon, whence the best woof dye is procured. The leaves are ground in a mill, like an oil-mill, into a paste, which, when quite uniform and smooth is laid in hoops to dry. The paste is mixed with the leaves in a mass: each addition is carefully joined to the preceding, so that the whole crop forms a long heap. A fermentation is soon established, by which the blue dye is separated. A black crust is formed all over the heap, which is in the gases produced. If any part of the crust is cracked, it must be immediately stopped up with some of the paste. It takes a fortnight to complete the operation. When the disengagement of phosphorated ammoniacal gas ceases, which is soon perceived by the smell and the crust is broken up, the inside, and small portions like bricks, of about one pound weight, are made up with the hands by pressure in a mould, when dry are fit for sale. As great attention is paid to the growing of the plant, it is best done by those who make a trade of it, and have the necessary experience. When the crop succeeds, the profit is very considerable; but, like all other crops, it is liable to many accidents.

Wodrow, on 21st March, 1707, over cut his small parish gave him the best plant of it for the accomplishment of his projected works, and though repeatedly invited to accept of more important ministerial charges, in Glasgow and in Stirling, he spent the remainder of his days at Eastwood, a large country seat, as a church politician; he punctually attended the ecclesiastical courts, and had much influence on their deliberation. He was chosen one of a committee of Presbytery at the commission of the Assembly in Edinburgh in the production of 1712, Scotland, on the convocation of the Union of 1707. He exerted himself in oppressing the act of 1712 for re-establishing patronage, the same which, after having been for 130 years a source of drains in the Church of Scotland, caused the great accession of the Church of England; and he was a member of the committee of five clergymen who, on the accession of George I., were deputed by the General Assembly to proceed to London, and urge the repeal of the obnoxious Patronage Act. Defeated in his object, he became engaged in his life in a great work, not finally recommended a subscription to the law as it stood, and in giving a beneficial effect to its operations. Yielding however on this point, he was one of those clergy who steadily resisted the impotence of the oath of abjuration; to which he was repeatedly in 1743, refused to be sworn at the same time among the best friends of the Hanover succession. Though he objected to the tendency of those involving a principle of civil government, to churchmen, he was at last, by preparing the publication of his articles of faith—that is to say, the articles of faith of his own church: and he conducted a long and laborious and obstinate controversy on the subject with the support of the independent principle in England and Ireland.

He died on 25th April, 1754, remaining to give a cursory notice of his literary labours. His History of the Sufferings of the Church of Scotland, from the Reformation to the Revolution, was published in two volumes, 8vo, in 1721-1722. A few years ago it was a scarce and high priced book. As a work, it was a publication which a publication in the library of the University of Glasgow. A considerable number of the Lives have been printed by the National Club, and a portion of the work is among the publications of the Wodrow Society. The late Mr. Wodrow was a minute historian. In tracing the sufferings of the Presbyterian nonconformists during the reign of Charles II., he undertook a subject a relation to which the bitterest feelings of indignation were still alive in the circle of society to which he belonged. The articles of his own church: and he conducted a long and laborious and obstinate controversy on the subject with the support of the independent principle in England and Ireland.

Wodrow, Robert, an antiquary and ecclesiastical historian, second son of James Wodrow, professor of divinity in the University of Glasgow, was born in that city in 1679. He studied at his native university, which he entered in 1691. While studying theology under his father, he was appointed librarian of the college, an office very congenial to his taste and nature. He was ordained minister of Eastwood in Renfrewshire, a parish situated between Glasgow and Paisley. His history from this period to his death is almost entirely that of his literary labours. He felt that the scenes of light duties of a retired and small parish gave him the best chance to use for the accomplishment of his projected works, and though repeatedly invited to accept of more important ministerial charges, in Glasgow and in Stirling, he spent the remainder of his days at Eastwood, a large country seat, as a church politician; he punctually attended the ecclesiastical courts, and had much influence on their deliberation. He was chosen one of a committee of Presbytery at the commission of the Assembly in Edinburgh in the production of 1712, Scotland, on the convocation of the Union of 1707. He exerted himself in oppressing the act of 1712 for re-establishing patronage, the same which, after having been for 130 years a source of drains in the Church of Scotland, caused the great accession of the Church of England; and he was a member of the committee of five clergymen who, on the accession of George I., were deputed by the General Assembly to proceed to London, and urge the repeal of the obnoxious Patronage Act. Defeated in his object, he became engaged in his life in a great work, not finally recommended a subscription to the law as it stood, and in giving a beneficial effect to its operations. Yielding however on this point, he was one of those clergy who steadily resisted the impotence of the oath of abjuration; to which he was repeatedly in 1743, refused to be sworn at the same time among the best friends of the Hanover succession. for which the narrator 'pledges his belief,' yet always as told him by some person worthy of credit: 'Mr. John Wode was preaching at a conventicle, and there was one cast a long line in mind. "Wode," he said, and told them he knew not the person that had done so, but he was persuaded they would be more persons at that person's death then they were hearing him preach that day. He added that he was a gentleman, and that he had been at Philip Stanfield's execution for murdering his father, and this Philip was the person that thus mocked Mr. Welsh in his youth.' Of course all the miraculous interpositions and special providences act in favour of the nar-

tory by the learned French refugee La Croze, who pub-
lished his preface to it in 1722, in the 'Bremer Ephemer-

rden. The work however remained in MS., which was

revised, abridged, and completed in others by Scholz.
The revised MS. became the property of the

library of Leyden, where it was examined by Wode, who

conceived the idea of publishing it. It is said that there

was then no printing to be had in England, so that the

work was written with Coptic characters, and the

university of Oxford liberty undertook to bear the expense.

Part of the work was already printed, when Wode was requested to make some additions to it, which he could only do for the three last letters of the Coptic alphabet; for in that part the only addition was a

the Advocates' Library amount to several hundred volumes. They are the collections made by the historian for the prosecution of his intended works. Many of them are original state-papers and letters, English and Scottich, bound up in volumes, with contents in Wodrow's hand-

writing. Others are copies taken by himself of documents of which the originals in many cases are not now to be

found. This collection, with his printed works, and many hundreds of long letters on ecclesiastical matters, are a standing illustration of his real untiring industry. In

May, 1841, the 'Wodore Society' already referred to was

instituted for the publication of the works of the fathers and early writers of the Reformed Church of Scotland.'

WOELPI, JOSEPH, a composer and performer on the piano-forte, who much distinguished himself by his talents during his short life, was born at Salzburg, in 1772, where he received instructions from Leopold Mozart, father of an actual composer. In 1787, after a short residence in Dresden, he was the brother of the less illustrious father of modern symphony.

After a short musical tour he reached Vienna in 1785, and

there successfully produced his first opera. He then visited

Dresden, Berlin, Hamburg, &c., and arrived in London in 1787, where he remained, composing and giving lessons.

Two years, then proceeded to Paris, and in all those cities

excited great admiration by his powers of execution. He

returned to England in a few months, and resided in his

capital till his death, which took place in 1811.

His hands, which were of gigantic dimensions, enabled him
to do, by means of their capacious grasp and strength,

what none of his contemporaries could accomplish, thus

making him, as it were, the precursor of the living Thalberg;

and his profound knowledge of the art, his untiring industry.

His compositions are numerous, ex-

ceeding to nearly every branch of the art, and all prove him
to have been a thorough-bred musician, though many were

written for the sake of sale, and others never ex-

posed and too difficult to be popular. Nevertheless,

he not indulged to excess in that habit which his

way was so prevalent with his countrymen, and which

would have been the ruin of his talent. He wrote, as a rule, in the style of modern German music, and probably would have made a reputation little inferior to that of the great musical triumvirate of modern Germany.

WOIDE, CHARLES GODFREY, was a native of Hol-

land, or of Poland according to Lechtreau-Gauthy, in the

Biographie Universelle,' who also says that he was born

in 1725, and that he studied at Frankfort-on-the-Oder and

Leyden. In 1770 he was invited to England, being ap-

pointed preacher at the German Royal Chapel, St. James's,

where he remained, composing and giving lessons. He was

appointed assistant-librarian at the British Museum, in the

department of natural history, and soon afterwards in the

department of printed books. The university of Copen-

hagen conferred upon him the degree of D.D. in 1785,

and in 1786 he was chosen a fellow of the Royal Society.

On the 6th of May, 1790, he was seized with an apoplectic

fit in the house of Sir Joseph Banks, and he died on the fol-

lowing day, in his apartment in the Narrow Street, near

Chandos. His will was written in Latin, and was left two

daughters by his wife, who died in 1782.

His principal literary productions are:—1, 'Mathurin

WOI 501  WOL
The next twelve years of his life were spent in attempting to establish himself as a physician at Truro, Helstone, and other towns in Cornwall. In this he uniformly failed, apparently on account of an invincible propensity to live as a practical humorist and satirise his neighbours. During his residence in Truro, some sonata, composition was sent to music by Mr. W. Jackson, of Exeter, and first introduced him to general notice. In 1778 he published his first composition in that peculiar style which not long after had obtained for him such a high and extended celebrity.—The Epistle to the Reviewers. It was during Wolcott's residence at Truro too that he detected the talents of the self-taught artist Opie. With this protégé he, in 1780, transferred his residence to the metropolis. Wolcott's first attempt of this kind, his art appearing in full maturity, is his Fine and Length I proposed to him to go first to Exeter and afterwards to London, and having lost an income of 300l. or 400l. by the change of scene, entered into a written engagement, by which it was agreed we should share the joint profits in equal division. This public service was so good and so services to the country, as he could now do for himself. That his pupil, as he terms him, should have done so is scarcely to be wondered at, for it does not appear that Wolcott contributed to the study of the joint he supported, and sustained any pecuniary loss by his change of residence.

No opening offering itself in the metropolis, either in physic or divinity, Wolcott was obliged to betake himself to sea, and to the support of his situation and ambitious. He suggested the subject of his first publication:—Lyrical Odes to the Royal Academicians for 1782, by Peter Findar, Esq., a distant relation of the Poot of Thebes, and Laureate to the Academy;" took the town by surprise. The justice of many of his remarks, the reckless freedom of the personality, the quaintness of the style, were something so entirely new that the work obtained immediate popularity. Encouraged by success the author returned to the attack in 1783, 1785, and 1786. But he soon discovered that, in order to keep alive his influence, he must bring into his line of criticism that the more daring he was in the selection of his objects of attack, the more would his works be run after, and the less would he incur any real danger. The king, ministers, opposition leaders, and authors, were assailed in succession. The popular public took a deep interest in his endeavours, and the more the reader discovered that they were different species; while Prince Maximilian Wied, perhaps still more practically conversant with the races of both continents, thinks that they are not specifically distinct.

With regard to the American Wolves, Colonel Smith remarks that whether they be distinct from those of the eastern hemisphere, or primeval varieties, is not yet satisfactorily established. The high authority of his book has been confirmed by his own experience; for they are different species; while Prince Maximilian Wied, perhaps still more practically conversant with the races of both continents, thinks that they are not specifically distinct. To this last-mentioned opinion Colonel Smith states that his own observations led him to subscribe; but he qualifies this statement by observing that while our ideas respecting the characteristics of species remain unsettled, the difference of conclusion appears, only formal.

In the succeeding year, the following wolves appear as distinct species,—the Common Wolf, Canis lupus, Linn.; the Mexican Wolf, Canis mexicanus, Desm.; the Red Wolf, Canis jubatus, Desm.; the Prairie Wolf, Canis bairdi, Harz. and; the Dusky Wolf, Lupus aethiopicus, Say.

Geographical Distribution of the Wolves. Colonel Smith observes that the typical Wolf of Europe and Asia, and the varieties belonging to this tribe in America, are described as animals occurring in the two continents from within the Arctic circle on the north, to Spain, and perhaps to Morocco on the west side of the Old Continent; to Syria, and beyond the Caspian in Asia; and to near the isthmus of Panama in the New World. Further south of these we lose track of these animals, which are replaced by an aberrant canine, the Red Wolf of Costa Rica, and in the first, by hyenas, the Painted Lycaon or Canis pictus, and perhaps by other species not yet fully developed. In China," says Colonel Smith, "the wolf has a very curious appearance, and is not an amiable one. His attempt to support himself by the labours of Opie has already been noticed. After all his biting satires on George III. and Pitt, he accepted a pension from the administration of which Pitt was the head—not to laud it (for praise was not in his nature) but to vituperate its opponents. He took orders and even officiated as a clergyman, though an avowed and profane unbeliever. He had a shrewd intellect; a just taste in the arts of design and music (a subject in which he was extremely expert), and he published an extensive and admirable work under the title "Pictorial Views," and some of his tunes have attained a permanent popularity; and his literary compositions have the finish of an artist, but his utter selflessness rendered these intellectual labours scarcely more elevated in him than his sensual appetites, which were equally regulated by taste and judgment. He was the perfection of a self-asserted vulgarity both in physical and intellectual respects.

Wolcott's constitution was probably naturally strong, for he attained to the advanced age of eighty-one. But for many years previous to his death he was the victim of asthma and acute jaundice, and his mind and body were, however retained its full powers. He lived only for himself; declined dinner invitations "to avoid the danger of loading his stomach with more than nature required;" but at the same time, because "to walk merrily in me to be groping around my drawing-room," because 'when up and in motion I am obliged to carry a load of eleven or twelve stone, while here I have only a few ounces of blankets to support;" and when out of bed he amazed himself with his violin, towards the end of his sight permitted, his crayons and pictures. He knew no aversion to receive notoriety-hunters who came to hear "Peter Findar," but evinced no desire for society. He left a considerable property to his relations. Wolcott died on the 14th of January, 1813, a week after his marriage in the churchyard of St. Paul's, Covent Garden.

(Annual Biography and Obituary for 1823.)

WOLF, Canis lupus, Linn. Lieutenant-colonel Colonel Smith makes Wolcot the first section of his first genus, Canis, of the Division of Carnivora or Canine纲, furnished with a round pupil of the eye.

In this section he comprises the common Wolf, Lycaon; the Black Wolf, Lupus *lycan*, the Dusky Wolf, Lupus *aethiopicus*, and the various species of the Mexican States of North America, Lupus *mexicanus*, Smith.

In the second section, Lycaon, or, as he terms his group, the Lyciscan Dogs, he places the North American, Lycaon *iurarius*; and the Caygote of Mexico, Lycaon *canus*, Cuv. The species of this section are described as being distinguished from each other by their coloration, and by a smaller size. In the American Canis, it appears in a much more developed form.
pieris of the dwelling were satisfied, from the well-marked impressions of their feet in the sand, that the animals came together, and perceived the place whence they had taken away two fish: double colour, each knew own. This theft, he adds, was moderate for two such carnivorous animals, but they did not choose the smallest. I do not know, continues the French traveller, that it has been before observed that the wolf goes (frayé) with the lion; but it is not extraordinary; there are daily proofs of it in this country, and every evening the wolf may be heard howling at the side of the lion. I have witnessed the same thing a hundred times in all my voyages on the Niger, and know, without possibility of doubt, that the lions and wolves are not exclusive of each other; there is nothing to fear. It is not that the size of the African wolf, which is much inferior to that of the wolf of Europe, makes any impression on the lion; it is only because the African flesh is not fit, I may say, to satisfy the latter: and what confirms me in this opinion is that I never saw the two lions which were kept in the middle of the village of Senegal attack the dogs which were exposed to them, or which they met when they were unchained; whereas they fell upon the first horse or child which came in their way.'

Le Vaillant and the French generally call the Spotted Hyena Loup tacheté; and the terms Tigre and Tigresse are used generally for any large spotted cat. Thus we use the term 'tigre du tigre' in the following passage: 'And the next sentence, where he says— Some days after this visit of the lion with the wolf, we received one from a Tigresse which came to the same place with her young one and also carried away two fish.' In the New History of Ethiopia, in describing a Descrabea, or, as they call it, the Kingdom of Abesenia, vulgarly, though erroneously, called the Empire of Prester John. In four books. By the learned Job Ludolphi, author of the Ethipien Lexicon. Made English by J. F. Gent. Folio, London, 1692, is the following passage: 'They are more cruel and fierce than lions, yet they savour mankind; yet they covet the Ethiopians before white men, and are more accustomcd to that sort of dyet. These two beasts have ears like five-leaved grass: It is almost superfluous to add, that the Tigre, properly so called, does not inhabit Africa.'

**EUROPEAN WOLVES.**

The Common Wolf—Yellowish or fulvous grey. Hair harsh and strong, longest below the ears and on the neck particularly the throat), shoulders, and haunches. Muzzle black: cheeks and parts above the eyes ochreous—grey in very old subjects. Upper lip and chin white. Eyes oblique, and shaded about the canthus. Ears black, pointed, and spotted with black; the tigress has her ears spotted with black; the tiger has them spotted with black, with fine black spots. Blackish ring on the crown, and blackish tail. Feet blackish. The ears are spotted with black, with fine black spots, like five-leaved grass: they are a beast of a dreadful cacity and boldness; by night they break into villages, and make dasteful massacres among the poor innocent cattle.'—Alvarez affirms that these butchers never happen in Medr-Bahr. It is almost superfluous to add, that the Tigre, properly so called, does not inhabit Africa.
that the Rosomak of the Lenas in Siberia, with shining black valuable fur, is probably the same.

**Habits, &c.**—The period of gestation and that during which the young remain blind will be found, with other particulars relating to the habits of the Wolf, in the article Dog. The female produces four or five at a litter; and although it is said, that until the young can see the female carefully hides them from the male, for fear he should devour them, it is certain that he hunts for them and brings them food, consisting for the most part of the smaller quadrupeds, partridges, moor-game, &c., after they have the use of their eyes, and that both parents take their offspring out to teach them to hunt as soon as they are strong enough.

**American Wolves.**

Dr. Richardson, in the "Fauna Boreali-Americana," observes to the Countrymen of the Old and New World, that they have been generally supposed to belong to a species—the Canis lupus of Linnaeus. The American naturalists have indeed, he remarks, described some of the northern kinds of wolf as distinct; but it never seems to have been doubted that a wolf, belonging to the genus of the European Wolf exists within the limits of the United States. Dr. Richardson goes on to point out that the wolf to which these characters have been ascribed seems to be the *lupus lapius* of Lewis and Clark: and according to them, this species inhabits not only the whole border of the Pacific and the mountains that approach the Columbia river, between the great fall and rapid basins, but is not found on the Missouri to the limits of the Platte. Dr. Richardson remarks that he has seen none of these Brown Wolves; but if their resemblance is close to the European Wolf as Colonel Smith, in给filsh's "Cuvier," states it to be, the Doctor has no hesitancy in saying that they differ decidedly from the wolf which inhabits the countries north of Canada.

In the "View Description of Virginia" (1649) wolves are mentioned among the beasts found there; and Lewis notices the Wolf in Carolina, and thus describes him:—"The Wolf of Carolina is the dog of the woods. The Indians had no other curs before the Christian era among them. They are of meeker frame, and are not large nor fierce as the European Wolf. They are not man-slayers, neither is any creature in Carolina unless wounded. They go in great droves in the night to hunt deer, which they do as well as the best of hounds, and may, one of them, consternate a wood. They are often so poor that they can hardly run. When they catch any prey, they go to a swamp and fill their bellies full of mud; if afterwards they chance to get any flesh, they will discharge it away. When they hunt in the night, that there is a great noise together, they make the most hideous and frightening noise that ever was heard. The fur makes good mats. The skin, dressed to a parchment, makes the best drab and gray cloth, and if tanned makes the best sort of shoes for the savage countries."

Catesby says:—"The Wolves in America are the true Wolf of Europe in shape and colour, but are somewhat smaller. They are more timorous and not so voracious as those in Europe; a drove of them were observed in a single day in very severe weather there have been some instances of the contrary. Wolves were domestic with the Indians, who had no other dogs before those of Europe were introduced, since which the breed of wolves and such dogs have become mixed and become intermixed. It is probable that the European dogs that have no mixture of wolf blood have an antipathy to those, that have, and many them whenever they meet. The wolf-bred not only do ferociously, and, with its tail between its legs, endeavor to avoid the other's fury. The wolves in Carolina are very numerous, and more destructive than any other animal. They go in droves by night, and hunt deer, hares, and most of the small game, barking and yawning night and day."

**Asiatic Wolves.**

The Wolves of Asia Minor are furious, but the colour is more predominant and has more red in it than that of the Italian Wolves.

Of the Indian Wolves, one, the *Hirana*, is described as being of a light fox-colour inclining to dun, not larger than a greyhound, slenderly made, but bony; the head and ears long, like those of a Jackal, and the tail long but not very hairy. The other, which is smaller, Col. Smith refers to his lyre-anan group. The last-named zoologist refers the black Desmoull of the mountains of Arabia and the south of Syria to the Wolf.

**American Wolves.**

Although the wolf is generally supposed to belong to the same species as the European Wolf, Dr. Richardson has described two species of the genus *Canis* that are distinctive of North America. The first is the *Canis lupus occidentalis*, which he describes as having a more slender build and a lighter coloration than the European species. The second is the *Canis lupus occidentalis* var. *Canis lupus occidentalis* var. *Canis lupus occidentalis* var. *Canis lupus occidentalis* var. *Canis lupus occidentalis*. This species is characterized by a greyish-brown coat with a white underbelly, and it is found in the western United States, where it is known as the "grey wolf" or "lone wolf."

Dr. Richardson also describes the "tundra wolf" or "wolf of the tundra," which is found in the Arctic regions of North America and is distinguished by its small size and light-colored coat, often tinged with red. This species is typically found in the high arctic tundra and is adapted to the harsh conditions of the Arctic climate.

**Asiatic Wolves.**

The Asiatic Wolves are generally larger than their European counterparts and have a more robust build. They are found in various parts of Asia, including the mountains of Central Asia, the steppes of Eastern Europe, and the tundra regions of Siberia. The colour of the Asiatic Wolf is typically a light, sandy-brown, with a distinctive white rump. The tail is short and bushy, and the ears are relatively large and pointed.

Dr. Richardson notes that the Asiatic Wolf is not as aggressive as its European counterpart and is less likely to attack humans. It is primarily a scavenger, feeding on the remains of larger animals such as elk and bison. In the absence of such prey, it will also hunt smaller animals such as rabbits and rodents. The Asiatic Wolf is also known for its keen sense of smell, which it uses to track its prey over long distances.

**American Wolves.**

The American Wolves, as described by Dr. Richardson, are distinct from the European Wolf in several respects. They are larger in size, with a more robust build, and have a typically grey or brown coat, often with a white collar. The tail is bushy and relatively short, and the ears are large and pointed. The American Wolves are found in various parts of North America, including the forests of the eastern United States and the grasslands of the western United States.

Dr. Richardson notes that the American Wolves are more aggressive than their European counterparts and are not as easily tamed. They are often considered to be a more solitary species, although some evidence suggests that they may form loose packs under certain circumstances. The American Wolves are known for their strength and agility, and they are skilled hunters of larger game such as elk and bison. They are also known to be effective scavengers, feeding on the remains of larger animals that have died of natural causes.
would be unable to preserve the game they kill from the wolves, if the latter were not as fearful as they are rapacious. The simple precaution of tying a handkerchief to a branch, and blowing up a horn, or making a loud noise by striking a stick against a large bough, in the wind, is sufficient to keep herds of wolves at a distance. At times however he says that they are impelled by hunger to be more venturous, and that they have been known to steal provisions from a settler at night, and to come under a traveller's bivouac and carry off some of his dogs. 'During our residence at Cumberland House in 1820,' continues Dr. Richardson, 'a wolf, which had been prowling round the fort, and was wounded by a settler, returned at a later hour of the day, whilst the blood was still flowing from its wound, and carried off a dog from amongst fifty others, that howled piteously, but had not courage to unite in an attack on their enemy. I was told of a poor Indian woman who was strangled by a wolf during the attack, was hastening to her assistance; but this was the only instance of their attacking human life, that came to my knowledge. As the winter advances and the snow becomes deep, the wolves are no longer able to hunt with success, suffer from hunger, and in severe seasons many die. In the spring of 1826 a large grey wolf was driven by hunger to prowl amongst the Indian huts which were erected in the immediate vicinity of Fort Franklin, and which the Indians considered had not been successful. It was found a few days afterwards lying dead on the snow near the fort. Its extreme emaciation and the emptiness of its intestines showed clearly that it died from inanition.'

We learn from the same excellent authority that the American Wolf builds its winter's lodge, not in a hollow in the earth, but in a cave, or in the ground; or it may be a large empty log, or even a fallen tree, or 

very common throughout the northern regions, but more or less abundant in different districts. 'Their foot-marks,' says Dr. Richardson, 'may be seen by the side of every stream, and a traveller can rarely pass a mile without crossing a wolf-track, or seeing the marks of their claw around him. They are very numerous on the sandy plains which, lying to the eastward of the Rocky Mountains, extend from the sources of the Peace and Saskatchewan rivers towards the Missourie. There bands of these animals feed on the game of the Indians, and prey upon the sick and straggling calves. They do not, under ordinary circumstances, venture to attack the well-grown animals; for the hunters informed me that they often see wolves walking through a herd of bulls without taking it. 'It sometimes, says he, meets a herd of wolves for the dogs of a party of Indians; and the howl of the animals of both species is prolonged so exactly in the same key, that even the practised ear of an Indian fails at times to discriminate them.'

The habits of the wolves of Melville Peninsula and the mode of capturing them by the Esquimaux are well described by Captain Lyon. Their boldness and ferocity must have been great. A fine dog,' says Captain Lyon, 'had just been purchased by a Mr. Elder, who was near to the spot, saw five wolves rush at, and attack it in an incredibly short space of time; before he could reach the place the carcass was torn in pieces, and he found only the lower part of one leg. The boldness of the wolves was altogether astonishing, as they were almost constantly seen amongst the hummocks, or lying quietly at no great distance in wait for dogs. From all we observed I have no reason to suppose that they would attack a single unarmed man, both English and Esquimaux frequently passing them without a stick in their hands; the animals however exhibited no symptoms of fear, but rather a kind of tacit agreement not to be the beginning quarrel, even though they might have been certain of proving victorious.'

Again, Captain Lyon thus notices their increased hardiness:—'The wolves had now grown so bold as to come alongside, and on the musk-ox houses, and the Esquimaux seldom did not couple of newly purchased Esquimaux dogs were confined, and carried them off, but not without some difficulty, for in the day-light we found even the ceiling of the hut sprinkled with blood and broken bones. One was given, but could not be allowed to go on the wolf as was laid and killed. It proved to be a female, which counted, Dr. Richardson remarks, for the sloughed wolves of not having been molested. Dr. Richardson further states that the buffalo-hunters P. C., No. 1749.
Esquimaux wolf-trap. It is made of strong slabs of ice, long and narrow, so that a fox can with difficulty turn himself in it, but a wolf must actually remain in the position in which he is taken. The door is a heavy portcullis of ice, sliding in two well-securued grooves of the same substance, and is kept up by a line which, passing over the top of the trap, is carried through a hole at the furthest extremity: to the end of the line is fastened a small hoop of whalebone, and to this any kind of flesh-bait is attached. From the slab which terminates the trap, a projection of ice, or a peg of wood or bone, points inward near the bottom, and under this the hoop is lightly hooked; the slightest pull at the bait liberates it, the door falls in an instant, and the wolf is speared where he lies.

The following varieties of North American Wolf are enumerated by Dr. Richardson:—
Variety A. Common Grey Wolf, Lupus griseus, the Makuygan of the Cree Indians, and the Amoral of the Equinamux.
Variety C. The Red Wolf, Lupus sictice.
Variety D. The Dusty Wolf, Lupus nubiles, Canis nubilus of Say.

The Dusty Wolf.

The Black American Wolf, Lupus ater, Canis lyopeus of Harlan.
The Prairie Wolf, Canis latrans of Say, Lyciscus latrans of Smith.

The animals which are thus distinguished have been long known, as Dr. Richardson remarks, to voyagers on the Missouri and Saskatchewan, as distinct from the Common Wolf. They are the Small Wolves of De Prez; the Prairie Wolf of Gass; the Prairie Wolf and Burrowing Dog of Lewis and Clark, and of Schoolcraft; the Cased Wolves of the Hudson's Bay Company's lists; and the Melouch-choggoneesh of the Cree Indians.

Geographical Distribution, Habit, &c.—Dr. Richardson states that the northern range of the Prairie Wolf is about the fifty-fifth degree of latitude, and that it probably extends southwards to Mexico. It associates, according to him, in greater numbers than the Grey Wolf of the same district; it hunts in packs, and brings forth its young in burrows on the open plain remote from the woods. Dr. Richardson further relates that on the banks of the Saskatchewan these animals start from the earth in vast numbers, upon hearing the report of a gun, and gather round the hunter expectant of the offal of the animal which he has slain. They are much more fleet than the Common Wolves. Dr. Richardson was informed by an experienced hunter who had resided for forty years on the Saskatchewan, that the only animal on the plain which he could not overtake, when mounted on a good horse, was the Prarie-homed Antelope, and that the Prairie Wolf was the next in speed. The Coyotl or Vulpes Idiens of Hernandez (Hist. Quadr. Novae Hisp., c. xiii.) appears to be the Coyote of the Mexican Spaniards, and is, 'most probably,' the Lyciscus cagottis of Smith. This appears to be the animal mentioned by Mr. Bullock; in his 'Six Months in Mexico,' 'Near Rio Pico,' says that traveller and assiduous collector, 'we shot several handsome birds, and saw a cajottie or wild dog, which in size nearly approached the wolf. He stood looking at us at a distance from the road, and it was not till a gun was fired at him that he deliberately moved off.'

With regard to this encounter, Col. Smith says that Mr. Bullock confirms the words of the Cappota, a very fierce kind of wolf, and that the individuals Mr. Bullock saw were in size equal to a bound, of a bushy rustic-grey, with buff-coloured limbs, and rather a scanty brush. This description, Colonel Smith adds, may coincide with a similar animal, which had not on the north-east coast of South America, only the tail was dark blue, with a white tip, and the under parts and feet were white. The Indians named it Aguaro, a name, Colonel Smith observes, applied to several species.

'This animal,' says Colonel Smith, 'measured about twenty-four inches at the shoulder, resembled a common wolf, but had a muzzle and the ears proportionally shorter; the body appeared to be rather long and more compared with the height; the ears, to the carpus and tarsus, were buff; the forehead, and back, clear grey; all the hair rather had a touch; the rest as before stated. In the 'Animal dom,' Baron Cuvier describes as a wolf, under the name of 'of Téxus,' one that is not a species; and we have little doubt but that the Coyotl, of Captain Beucherie, observed by him the banks of the Sacramento River, in California, 37° 43' north, and 122° west, is again the same animal, without adding that the coyote, or coyote, is given to it seems to imply a smaller species.'

Hernandez describes the Coyotl to be an unknown to the Old World, with a wolf's head, large, and pallid eyes, small and sharp ears, a long and not thick muzzle, numerous long white, or black claws, a very rough and thick tail, a nimous bite, proaching in form to the Fox, to which genus it is to be referred, and intermediate between it and in size; for it is twice the size of the fox and long, whereas it is said to attack and kill not only and similar animals, but stags, and sometimes even men. It is covered with brown and white long hair, is in hunting and vulpine in its manners, and so prone an arrow of wrongs, and so prompt to its prey, that it will recognize the robber after many hours will follow him, and sometimes set upon with its own kind, &c. It is however graceful to its beauty. It lives in many places of New Spain, and exposes those traits of character which are colder. It feeds upon the deer, hog, maize and other frumentaceous vegetables, and cane.

The Aguaro Guazu of D'Azara is the Canis jubatus, Cuvier, the Leop rouge of the French, the Pecos, of The Prince de Paulitra; the Prarie Wolf, and the Mexicano, of Smith.

The Canis jubatus, of Smith, of D'Azara thus describes this Red Wolf, to which Payaguas Indians give the name of Pataungu, and Chilian of that of Culpen. In Mexico, he says, the goes by the appellation of Orconomus. It is known by the name of a species, which it appears to have in common with the Coyote, or Cojut, which is said to be the same.

Length of an adult male exactly five feet, that of a tail nineteen inches, the hairs being four inches long. Height in front two feet ten and a half inches, and two feet eleven inches; circumference close to the feet wanting half an inch of feet, of the middle neck a foot, and of the head, before the ears, one and a half. The ears six inches high, in their part four, erect, but not exactly sharp, and very thick. From the roots of the ears to the tip, it begins to shrink, when it comes to the inner angle of the ear five inches; whiskers two inches and a half long, and black, upper jaw projecting an inch; the canine teeth are long, although they were very much worn, and scarce in numbers; the ears are the almost equal thickness to the tip. Under the great white spot; long hair within the ear and half tail of white also. Fore and hind feet to the lower jaw from the crown of the head, extremity of upper jaw black: rest of the ear yellowish-red. Mano. commencing at the aspect of continuing erect till beyond the shoulder, five inches, three-fourths long, and in the first half of the body, ten inches, black in the remainder towards the tip. Hair all over the body, including the belly, except the lower part.
D'Azara observes that it is either completely flattened or very rough, and would make very good carpets. Hair of the tail rather bushy and of the same length as on the body.

D'Azara adds—"At different times, which were identical, the smallest towards the end of September, which appeared to him to have been helped at the end of July or the beginning of August. D'Azara's friend Noseda caught another about two months after this, of the same colour, and made somewhat like a greyhound, but more robust; their aspect is mild, and their disposition gentle and peaceable: their strength is so great, that in combat the mastiff or bull-dog is far from being equal to them. They mostly seize their antagonists by the back, which gives them, which their great size generally enables them to do with ease."

The author of the 'Sportsman's Cabinet' (1804) remarks that the Irish greyhound is so rarely to be seen, that it is a matter of doubt whether one of the pure and unmixed breed is to be found even in the most remote part of the country from whence they are supposed to have derived their name. It is affirmed, he adds, by the best and most respected authorities, that the Danish dog, the Irish greyhound, and the Common greyhound of this country, though they appear so different, are but one and the same race of dog.

Next to this in size and strength Bewick places the Scottish Highland greyhound or wolf-dog, used by the Highlanders in their parleys. He states—"The Wolf-dog, a favourite sport of the noble, is fitly managed in parleys. Walter Scott's 'Maida' appears to have been a noble modern example. This is probably the race to which Beothius alludes as 'genus venaticum cum celeritatem tum audaciam simum,' praising its boldness not only in attacking wild beasts, but the wolves of the chase.

Colonel Hamilton Smith, speaking of the Irish greyhound, 'C. Hibernicus,' remarks (1840) that this antique race was originally, we may presume, the same as the Scottish; and, according to some opinions, was not found in Ireland in its great number and perfection until the thirteenth century, when the Normans began to infest the coasts. After observing that no such race is recorded to have existed antelently in Scandinavia or Denmark, and that its earliest colour was buff or pale yellow, in that respect also approximating the breeds of the East, and that the mystical bitch in Dantal's lore appears to refer to this species, both in Britain and Ireland, he expresses an opinion that the ancient race, like the Scottish, may have been crossed with the greyhound by the Normans. This curious circumstance, may have increased to the great stature since so much admired.

'Of the specimens we have seen,' says Col. Smith, 'and the figures published, no two appear now exactly alike in the structure or colour of the head. The greyhound may also be said to have been crossed with the antient species; and from this circumstance, no doubt, arises the difference in qualities ascribed to them. Still this dog, as large in Western Europe, and the extinction of the wolves in Ireland may, in part at least, be justly due to its exertions. The bitch kept by Buffon killed the male wolf she was bred up with, which proves that one was more than a match for that fierce animal. Lord Alazon is said to have kept the last dogs of this race, and it was one of his that Mr. Lambert describes in the 'Linnean Transactions.' But we heard that Lord O'Neill likewise had some; and, still later, that Mr. Hamilton Rowan used often to appear in Dublin with a couple of these majestic beasts."

WOLF, HIERONYMUS, a German scholar of the sixteenth century, was born on the 13th of August, 1516, at Deltingen, and belonged to a noble but reduced family. From his early youth, he aspired to be a churchman, but his father, whose means were very limited, and who also thought the delicate constitution of his son unsuited for a studious life, tried to dissuade him from it. His son at last gave way, and resolved to study law; but his early studies in this way again changed his determination, and he accordingly went to the university of Tübingen, where he became a pupil of Camerarius and J. Scheeg. As his father could not supply him with money, he was obliged to borrow books from friends, and sometimes from one of the professors. He was however soon tired of this situation, and went to Würzburg.
where he got a place as clerk in the bishop's office. Here too he did not remain long. He resigned his post and went to Wittenberg, where he attended the lectures of Melanchthon and others. He began to translate some Greek authors into Latin, which was his favourite occupation. In 1539 he went from Wittenberg to Nürnberg, where he acted for a time as assistant-master in a public school. There he was recommended to the gymnasium at Mühlhausen, on the recommendation of Melanchthon: but his restless disposition did not allow him to remain there more than two years; he resigned his office and returned to Nürnberg. After having stayed there for some time among which he made himself very familiar with private lessons, he went to Strassburg. The next few years he spent partly at Strassburg and partly at Basle, being all the while zealously engaged in preparing his editions of Isocrates, Demosthenes, and Aeschines. From Strassburg he went to Paris, and after a short stay there he returned to Basle. He now took his degree of Master of Arts, and then went to Augsburg, where he at length found a resting-place. Anton Fugger received him into his house, made him his librarian, and employed him in carrying on his Latin correspondence. After having been in this situation for six years, from 1551 to 1557, he was appointed professor of Greek in the gymnasium of Augsburg. Soon after, he was appointed to the rectorship of the gymnasium, and obtained in addition to it the office of librarian of the public library of the city of Augsburg. These offices he held until his death, on the 8th of October, 1559.

Hieronymus Wolf was a man of very extensive learning, and was particularly distinguished for his knowledge of Greek, which he is said to have written with greater facility than Latin. Some of his works have Greek prefaces, which show that he possessed a perfect knowledge of Greek. His Latin translations from the Greek are more faithful and correct than elegant. He was a man of a very discontented disposition, and was often in a state of melancholy. He had scarcely any friend, and was never married. He was fond of astrological speculations. Among his editions and translations of Greek writers the following are the most remarkable: 1. An edition of Nicephorus Gregoras, with a Latin translation and notes, Basle, 1552, fol.; 2. An abridged edition of Suidas, with a Latin translation, Basle, 1561, fol.; 3. An edition of Demetrius Phalerus, with a Latin translation, the commentary of Ulpian, Greek scholia, various readings and notes, Basle, 1572, fol.; 4. A very good edition of all the works of Isocrates, with a Latin translation and notes, Basle, 1563, fol. Among these three Athenian scholars the best is the among his editions of ancient authors; 5. An edition of Zonaras, with a Latin translation, for which he collated five MSS., Basle, 1557, fol.; 6. The first edition of Nicetas Acinnatus, with a Latin translation, Basle, 1556, fol. He also wrote several works on grammar, in which however are not of much value, and some original treatises, such as 'Dialogus de Usu Astrologiae,' and several others.

(From, Miscellanea Historiae Philosophicae, &c.; Jöcher, Allgemeine Gelehrten Lexicon; Fr. Passow, Vermischte Schriften, Leipzig, 1843, 8vo.)

WOLF, JOHANN CHRISTOPH, a learned Lutheran divine, was born on the 21st of February, 1563, at Wernigerode. His father was corps-chaplain. In 1566 the family removed to Harburg, where the father died three months after his arrival; but young Wolf found a friend in Johann Albert Fabricius, who received him into his house, allowed him the use of his extensive library, and also gave him the tuition of his studies. Thus, the young man availed himself of these opportunities, and before he had attained his twentieth year, and before he went to the University, he had not only read the most important among the ancient writers, but also the whole Commentary of Eusebius on the Old Testament, and many other books. He drew up a list of the authors mentioned in that commentary. This list is printed, with a few improvements, in Fabricius' 'Bibliotheca Graeca' (vol. i., p. 457-501). Subsequently he made a similar list of authors referred to in Ireneus, Tertullian, Origen, and Rhesus, which is likewise printed in Fabricius' 'Bibliotheca Graeca' (vol. iv., p. 279-286). Having obtained a scholarship, which enabled him to continue his studies, he went in 1576 to the University of Wittenberg.
Friedrich, a professional musician; and after he himself had given him all the theoretical and practical instruction he was capable of, he sent both sons to the learned organism Schröter, who also instructed them in mathematics, a science to which Friedrich August had an aversion throughout life. But Wolf's plan was inadvertent, for by chance Friedrich; for although Friedrich August was fond of music, sang and played several instruments, yet he regarded the art only as an elegant amusement, and was resolved to follow the course of study which he had commenced at Harz, and had adhered to the university of Göttingen to study philology exclusively. He always prized private study more than any other; and in consequence of this he was highly irregular in school. The learned professors of Göttingen fully observed this inclination in Wolf, and on one occasion, when Heyne was going to lecture on Pindar, and Wolf wanted to enter his name as one of his hearers, Heyne refused to admit him. From this moment Wolf avoided Heyne, and did not even attempt to become a member of the philosophic seminary, though in a financial point of view it would have been a material assistance to him. But Wolf nevertheless lived happy and retired at Göttingen, and he made up the deficiencies in his finances by giving private lessons to other students. Being invited to the Harz Mountains, he fact, that in order to have an English book which he might read with his pupils, he published, in 1778, an edition of Shakspere's 'Macbeth,' with explanatory notes. Heyne was one of the men of paramount influence in all scholastic matters at Göttingen; and Wolf, having been presented to him a dissertation on Homer, in which he explained some points on which he ventured to differ from Heyne; but Heyne peremptorily refused to read it.

In 1779 Wolf left Göttingen, and was immediately after appointed teacher in the paedagogium at Ilfeld. Here he made himself first known to scholars by his edition of Plato's 'Symposium' (Leipzig, 1782, 8vo. ; a second edition appearing in 1784, with a learned work on the production of German. The manner in which Wolf treated his author met with general approbation, and attracted the attention of the Prussian minister, Baron von Zedlitz. In consequence of this publication Wolf was appointed, in 1782, reader of the public school at the foot of the Harz mountains. In the year following he received two invitations, one to the office of rector of the gymnasium at Gera, and the other to that of ordinary professor of philosophy in the university of Halle, and rector of the paedagogium, at Copenhagen, and Zedlitz, the friend of his own. This edict contained also the following of the 'Monumentum Ancyranum,' and of the 'Fasti Praenestini.' 3. A collection of his sma...
commanded the sea and Amherst the land forces. The brunt of the French fire in landing before Louisbourg was borne by Wolfe. It was characteristic of Wolfe that he went to the front in the heat of the action, telling his officers to take care of centre and right divisions being mere fees to distract the enemy. The after operations of the siege were also in a great measure conducted by Wolfe; and it was an honourable trait in the character of Amherst that, in his dispatches, he allowed his brigadier the full credit of all the actions. The landing was effected on the 6th of June: Louisbourg surrendered on the 26th of July. Wolfe soon afterwards returned to England.

In 1759 Wolfe was sent out against Quebec by Pitt, who had resolved to deprive the French crown of its most important settlements in America. The command of the sea-forces was intrusted to Saunders; the command of the land-forces (7700 men, including provincials) was given to Wolfe. The embarkation arrived at the Isle of Orleans on the 26th of June: the fort of Niagara had been submitted to the English under Amherst the day before. In August Wolfe issued a proclamation to the Canadian peasants, informing them that his forces were masters of the river, while a powerful squadron under General Amherst threatened their country from the interior, calling upon them to observe a strict neutrality during the struggle between the French and English crowns, and promising to protect them in their possessions and the exercise of their religion. Wolfe had time to reconnoitre and to reorganise the troops which he had in the province in Quebec, which he had fortified in a masterly manner. The months of July and August were spent in repeated unsuccessful attempts to force the enemy to battle. The Canadians, who had no reason to doubt Wolfe's determination to carry their works, began to repair the breaches, which prevented them from advancing. Wolfe, with his usual prudence, waited for the enemy to come to him.

The feature of Wolfe's character most dwelt upon by his contemporaries was his ability and skill as an engineer of enterprise. His skill as a disciplinarian however, the pains he took to ascertain the real state of affairs at Rochfort, led the arguments by which he supported the proposal of a descent, and, above all, his letter addressed to the King on the 19th June, his head-quarters having been on the 2nd of September, show that this quality was combined with an observant and deliberate mind. Enterprise was with Wolfe the result of perfect and laboriously attained knowledge, without which the latter would be but a name.

It is to be regretted that the correspondence of Wolfe which is known to exist has not been given to the world. It would be instructive to the military men, for his character as a soldier was almost perfect, though the field in which his talents were developed was a narrow one. The task was undertaken by Porty and afterwards by Gieg; but relinquished by both from unexplained difficulties which intervened. Michaud, Jeune, is in error when he says, in the 'Biographie Universelle,' that Life and his son of the 18th century, had been the work of a secret correspondent in 1827; it was only announced. The author of the article 'Wolfe, James,' in the 'Encyclopædia Americana,' has without restraint and in the best manner, copied Michaud's sketch, and the task is at an end. The only materials for the Life of Wolfe contained in the 'Annual Register,' edited by Burke; in a very slender 'Life of General James Wolfe,' attempted according to the rules of eloquence,' by a writer who designates himself 'J. P.' in the 'Military Miscellany.'

The death of Wolfe made a deep impression in England. The most touching instance is mentioned by Burke:—A little circumstance was talked of at that time, and it deserves to be recorded, as it shows a fairness of character and a justness of thought in the heart of people that is rarely met with, even amongst persons of education. The mother of General Wolfe was an object marked out for pity by great and peculiar distress; the public would pierce her mind with a peculiar affliction, who had exp...
enced the dutiful son, the amiable domestic character, while the world admired the accomplished officer. Within a few months she had lost her husband; she now lost her son, her only child. The populace of the village where she lived unanimously agreed to admit no illuminations or fireworks, or any other sign of rejoicing whatsoever near her door. It was recommended, by all her friends, she should not be allowed to sue out over her grief. There was a justness in this, and whoever knows the people that made no small sacrifice on this occasion.'

James Wolfe fell in his thirty-fourth year. His remains were deposited in the Old Burial ground at Edinburgh, and were erected to his memory, in 1769, by the gentlemen of his native parish: a public monument in Westminster Abbey was voted by the House of Commons in 1759, and opened to the public in 1773; a marble statue was voted by the Academy of Athens for the public college at Bordeaux; a small statue and a tomb were voted for the poet, in the Pantheon, Paris; a large tapestry was ordered for the Church of Scotland, Edinburgh; a gold medal and a copy of the 'Lexicon' was given; a 12mo volume entitled 'College Recollections,' published at London in the same year with Archbishop Wharton's work, but we believe, some months before it. The 'Remains' (filling 368 pp.) consist principally of Fifteen Sermons, an appendix of miscellaneous thoughts and other fragments, and some juvenile poems, some letters, and other compositions inserted in the Memoir, which, including these, occupies nearly half the volume. Wolfe's literary reputation rests on his famous ode entitled 'The Burial of Sir John Moore,' which he composed in 1817, on reading Southey's prose narrative in the 'Edinburgh Review,' and which first appeared soon after with his initials, though without his knowledge, in the 'Newry Telegraph,' from which it was immediately copied into the London papers, and from those of Dublin. The poem, which in the pathos of a noble simplicity has rarely been surpassed, drew much attention from the first; but its authorship remained unknown, except to a small circle of Wolfe's friends or associates, until the question came to be publicly discussed in consequence of a high encomium stated in Captain Medwin's 'Conversations of Byron,' published in 1824, to have been passed upon it by his lordship. The lines were attributed to various writers; and claimants to the honour of having produced them have started up from time to time, some even within the last few years. But the whole of these attempts to defraud the true author of his rights have been persistently refused.*

There are some lines of Wolfe's written to the popular Irish air 'Granmarche,' which in their kind are little inferior in merit to those on the burial of Moore.

WOLENBOTTEL is one of the six circles of the duchy of Brunswick, containing 18,000 families, and 50,000 inhabitants. Wollenbottel, the capital, is situated in 52° 9' N. lat. and 10° 32' E. long., in a low marshy spot on the banks of the river Ocker, which flows through the city. It was formerly well fortified, but the works having fallen into decay are now restored. The city has been converted into public walks. It is divided into three parts, viz. the citadel, or formerly fortified part, and two suburbs, containing altogether about 10,000 inhabitants.

The town is, the whole, without business, the most part, straight streets, all well paved. Till 1744 it was the residence of the dukes, in whose palace there was a manufactory of tapestry and a theatre. Opposite the palace stands the fine building erected by Duke Augustus in 1723, the model of the Painted Hall at St. Alban's, and the first example of the ground-floor the Ducal Riding-school, and above it the celebrated library, which was rendered still more famous by the 'Wollenbottel Fragments' published by its librarian, the learned G. B. Lessing, to whom a monument is erected. This library is probably the earliest impressions and 10,000 MS. It seems that no good catalogue has been made, for some accounts say that it consists of 270,000 volumes, others of 200,000, while others again reduce it to 140,000; among them there is a large collection of Bibles, and a representation of St. Mary which that of St. Mary is remarkable for its size; an ancient arsenal, now used as barracks; a large poor-house; an orphan asylum; a good gymnasium; and several schools. The inhabitants have a considerable trade in yarn, and they also manufacture linen, leather gloves, japanned wares, paper-hangings, silk, diaper, tobacco, liquors, and vitriol; there are likewise some taverns and distilleries. Wollenbottel is the seat of several public offices, for the whole duchy, of the consistory court, of the bishop of Wolfenburck, and of the bishop of Waldeck, Lippe, and Brunswick. The pretty country seat Antoinesenhuizen, having fallen into decay, has been pulled down. Near the town are the two villages Ober and Niederstalak, where the beautiful ducal palace of Salzthum, formerly stood. It is in the park of which a fine gallery of paintings which it contained (sixty of the most valuable of which were carried away by the French in 1806, but restored, we presume, in 1815) has been assigned to Brunswick, where it depicts the whole American war, together with the titles of squablers and other works of art.

(Brockhaus, Conversations Lexicon; Hassel, Handbuch der Geographie, vol. 1, Leipzig, Handbuch, by Hörschelmann; Cannabich, Lehrbuch der elektrischen Wissenschaften.)

WOLFF, JOHANN CHRISTIAN VON, a celebrated German mathematician and philosopher, was born at Breslau, January 24, 1679, and at an early age showed a taste for the acquisition of knowledge. His father, who was a
brewed, strongly encouraged him in this disposition; he became his first preceptor, and, having instructed him in the Latin language, he sent him to the public school of the town, in order that he might have the benefit of the best masters which it afforded. The youth there studied diligently the philosophy of the age, and he acquired such a facility in the progress of the learning that he is said to have become the rival of his tutors; but before he was twenty years of age, having obtained information of the revolution which the writings of Descartes had begun to produce in the schools, he was actuated by a strong desire to be initiated with them; and application to the Cartesian philosophy was a determination to cultivate mathematical science for the purpose of founding on its principles a system of metaphysics. With this object he passed through a course of mathematics at the University of Jena, and he afterwards went to Leipzig, where he resided during three or four years. Here, in 1703, he began to deliver lectures; and in the same year he published two tracts, one entitled 'De Rotis Dentalis,' and the other 'De Algorismos Infinitesimali Differentiali.' The ability displayed in these dissertations procured for Wolff the esteem and friendship of the learned men of his country; he became intimate with Tschirnhausen and Leibnitz, and by them he was encouraged in his enterprise to pass to Germany, a national philosophy which might replace that of Aristotle as then understood. He at first intended to enter the church as a profession, but he was finally induced to seek an appointment in fulfilling the duties of which he might continually advance his knowledge, and to seek such positions as were a candidate for a professor's chair, and in 1707 he was appointed to give instruction in pure and mixed mathematics in the University of Halle. It was while he held this post that he published, entitled 'De Mechanico Mathematico et philosophico' and his 'Elementa Matheseos Universae,' of which last work an enlarged edition was published at Geneva between the years 1720 and 1741, in five volumes, 4to. The first volume contains the following subjects:— 'Commentationes de Arithmetica, Algebra, Geometria, Trigonometria plana et sphaerica.' The second, 'Mechanica cum Statica; Hydrostatica, &c.' the third, 'Optica; Perspectiva atque Astronomia.' the fourth, 'Geographia; Chronologia; Gnomonica; Pyrotechnia et Architectura.' and this fifth, 'Commentationes de Prinicipiis Scriptorum Mathematicorum.' &c. He also published at Leipzig and Frankfort, in 1728, 'Tabulae Sinuum atque Tangentium tarn naturalium quam artificialium, una cum Logarithmis numerorum vulgarium, &c.' Being a member of the Philosophical Society of Geneva, and in 1718, he was appointed to a chair of mathematics and physics, which were inserted in the 'Acta Eruditorum,' and in 1710 he was elected a Fellow of the Royal Society of London.

In 1712 and 1713, Wolff was almost exclusively devoted to the study of metaphysical and moral philosophy; and between the years 1712 and 1723 he wrote his 'Thoughts on the Powers of the Human Mind;' on the Deity and the Universe; on the Operations of Nature; and on the Search after Happiness; and, as a sequel to the last, 'Thoughts on Society as a means of advancing Human Happiness.' These works were published separately in the German language, a medium till then unemployed in treating such subjects, but the circumstance produced the best effects by providing a medium of communication between those who are devoted to mathematics and physics, and those who are interested in the advancement of knowledge. In 1725, however, he was invited back to Halle; and, in 1733, appointed a professor in the University of Brunswick; and in 1737, he was elected a member of the National Academy of Sciences at Paris.

On his return to Halle he was made privy-councilor, vice-chancellor, and professor of international law; the king afterwards made him Chancellor of the University, and sent him to Brazil as a representative of the Empire; and at the conclusion of his mission, the inestimable investigations which he made in the hands of all the German students, his oral instruction were no longer necessary. Being attacked by the gout in the stomach, he died, having borne his sufferings with fortitude and Christian piety, April 9, 1744, in the 76th year of his age.

The merit of Wolff consisted in a correct and methodical arrangement of the subjects of philosophical science, rather than in discovery. He borrowed freely from his immediate predecessors, Descartes and Leibnitz, and even from the writings of the Stoics. He employed the methods of mathematics to precise methods which are employed in philosophy, he appears to have overlooked the want of homogeneity in the elements of the former branch of science, which renders it one of the most abstract reasonings. In stating a philosophical proposition which is perhaps self-evident, he often exhibits a tedious demonstration in order that he may show its dependence on some more general theorem which precedes it; and these demonstrations are remarkable for their extraordinary pedantry.

Wolff divides human knowledge into three parts, historical, philosophical, and mathematical: in the first he includes everything relating to material as well as intellectual being, that is, whatever is cognizable by the senses.
or by internal conviction. The second he considers as comprehending the reasons of things; and he states its object to be the explanation of the reason that what is possible may be realized. His third division constitutes the knowledge of quantity. He divides psychology into two kinds, which are designated rational and empirical, and the former is distinguished from the latter as the science of things possible relatively to the soul only. He defines science in general, the faculty of demonstrating.

WOLFF, PIUS ALEXANDER, one of the most distinguished German actors of the present century, was born in 1704. He belongs to the line of the learned professions, but his own inclination, as well as his natural talents, led him to the stage. In 1804 he was one of the actors engaged at Weimar, the theatre of which place was then regarded as the model for all German theatres. Schiller and Goethe were themselves actively engaged in conducting the theatre and training the actors. As Wolff was a man of much greater talent than the majority of actors, Goethe took especial trouble with him, trained him on sound artistic principles, and afterwards declared that Wolff had become an actor quite to his mind. Wolff devoted himself especially to the performance of tragic characters and youthful heroes, which he acted to perfection. His performance of Hamlet, the Marquis Posa, Max. Piccolomini, Weislingen, Orestes, and Tasso, made such an impression in Germany, that to this day he is considered the most perfect actor of which other actors are measured. At a later period he occasionally also acted comic and harmonious characters, in which he was much admired, though tragedy was at all times his peculiar field, in which he was unsurpassed. In 1816 he became a member of the royal theatre of Berlin.

He died at Weimar in 1828. During the latter years of his life he wrote several dramas, which were well received, and some of which are still favourite plays in Germany. Three of them, 'Caesar,' a comedy, 'Dicht im Pflicht,' and 'Preciosa,' form a separate collection which he published under the title 'Dramatische Spiele,' Berlin, 1823, but the collection was not continued, and his other plays appeared separately at different times. 'Preciosa' has become celebrated by being taken by C. M. von Weber for one of his most popular operas. His other plays are—'Der Hund des Aubri,' a farce, (Berlin, 1822); 'Der Mann von fünfzig Jahren' (Berlin, 1830); 'Treue siegt in Liebenesetern,' and 'Der Kamerdiener' (Berlin, 1838).

(Gervinus, Neuere Geschichte der Poet. National-Literatur der Deutschen, ii, p. 559; Brockhaus, Conversations-Lexicon.)

WOLFRAM VON ESCHENBACH, a Minnesänger, who lived in the first part of the thirteenth century, is considered the best German poet of his time. He was probably born at a castle called Eschenbach, which seems to have been situated in the Upper Palatinate, and he was descended from a noble family. After having been a knight, he retired to the monastery of St. Sebald, where the emperor received him with equal satisfaction in their camp and at their court. He was present at the famous poetical festival on the Wartburg. Towards the end of his life he retired to his native country: he died in 1220.

Wolfram von Eschenbach is the author of the 'Parzival.' Of his numerous productions the greater part however are lost, but his principal poem has most luckily been preserved in MS. at St. Gallen and at some other places. The poem is entitled to the title of one of the most beautiful of French and Provençal models—the holy Grail being the marvellous object which the hero of the poem, Parzival, pursues in a long course of adventures. He at last becomes king of the Grail, and thus enjoys the parest happiness which man can enjoy. There is an episcopal tendency in the poem, but it would be incorrect to call it an epic; full of deep thoughts on the destiny of man, on the mysterious nature of his soul, on his religious and moral duties, it belongs to a class of poems which are rare in the literature of the world, and of which the 'Parzival' may be considered as the most striking specimen. The 'Parzival' was written about 1205. It was first printed in 1477, fol., in an incorrect and mutilated edition, which was reprinted and somewhat corrected in the first volume of 'Sammlung Alldiotter Gedichte,' by Müller, who collated the MS. of St. Gallen. The other extant works of Wolfram von Eschenbach are, 2, 'Tituler,' first printed in 1477, 4to, a fragment of an introductory poem to Parzival, and in Gervinus's opinion the finest specimen of ancient German poetry, which must not be confounded with another poem, likewise called 'Tituler,' which was once incorrectly attributed to Wolfram; 3, 'Willehalm von Orange' (William of Orange), in Manesse's collection of Minnesingers. The place there are also added, and the author of the poem is unknown. An excellent critical edition of all the extant productions of Wolfram von Eschenbach was published by Lachmann, Berlin, 1833, 8vo, who has added a valuable introduction to the Life and Works of the author. Wolfram, however, a considerable writer, was not the greatest. In his style is simple, clear, and elegant, and the difficulties which exist are rather due to the mystical tendency of the author and his transcendental ideas, than to a want of those qualities which constitute a great poet.

WOLFRAM. [TURGENJ.]
attained any degree of excellence in painting, and he has the additional honour of having been the master of Albert Dürer. Wolgemuth's wood-cuts are the oldest prints of that class in Germany of which the artist is known, and they are extremely scarce. Wolgemuth's paintings are likewise scarce; there are two in the Augustinian church at Nürnberg, another in Our Lady's chapel, and a Last Judgment in the town-house of the same place; and one in the church of Schwabach for which he was paid, in 1507, 80 florins. For that period a very great sum; some years after this the celebrated Amberger charged the emperor Charles V. for his portrait only 35 florins. There is also a valuable work by him in the Imperial Gallery of Vienna, painted in 1511; another in the Louvre at Paris, and in the Pinakothek at Munich there are five pieces by Wolgemuth. He died in 1510, aged 85.

The king of Bavaria possesses a portrait of Wolgemuth, painted in 1516, in his 82nd year, by his pupil Albert Dürer; this is inserted upon the back of the picture.

Wolgemuth's style has the defects of the works of art of his age, especially in design; his works however are carefully finished, exhibit much expression, and in the draperies are superior to the works of many of the eminent German painters who succeeded him.

Wolgemuth and Pleydenwurff cut in wood the illustrations of a curious and celebrated old work in folio, known as the 'Nürnberg Chronicle' of Hartmann Schedel, a physician. It was published first in Latin, in 1493, eight years after the death of its author. His autograph is translated and engraved by a woman in the following year. The cuts consist of views of towns and portraits of eminent men. The Latin edition is the better; the title commencements—Liber Chronicarum per viam Epitomatis et Brevisarii compilatus, &c.

WOLKONSKIT. Amorphous. Structure compact, transparent, conchoidal, with a light greenish-blue to light emerald-green. streak bluish-green and shining. Opaque. Nearly dull. Specific gravity 2.2. It is so extremely fragile that it readily falls to pieces on a slight blow. It is found at Perm in Russia.

WOLLASTON, WILLIAM, author of 'The Religion of Nature demonstrations' was bom at Staffordshire, on the 26th of March, 1669. He was descended from an old and considerable Staffordshire family, but belonged to a younger and a poor branch of it. 'When he was in the tenth year of his age, a Latin school was opened at Shenston in Staffordshire, where his father, a private gentleman of a small fortune, then resided; and Mr. Wollaston was immediately sent to the master of it for such instruction as he was capable of giving him, and continued near two years under his care. Afterwards he was sent to Lichfield school, in which a great deal of learning happened, and the magistrates of the city turned the master out of the schoolhouse. Many scholars followed the ejected master; and Mr. Wollaston amongst the rest. He remained with him till he quitted his school, which was before the death of Mr. Wollaston; and thence, the scholium being ended, he returned into the free-school, and continued there about a year. This was all the schooling Mr. Wollaston ever had.' (Clarke's Life of Wollaston, prefixed to his edition of the 'Religion of Nature,' 1793, p. iv.) On the 19th of June, 1724, he was entered a pensioner at Sidney Sussex College, Cambridge, where he resided almost without interruption until the 29th of September, 1681, by which time he had taken his Master of Arts' degree and deacon's orders. He was disappointed in not obtaining a fellowship in his college, for which he had laboured with great diligence, and in the hope of obtaining which he had submitted to much inconvenience from poverty during his residence in the university. On leaving college he took the situation of assistant-master at Birmingham school, and shortly after he joined the school he obtained a lectureship in a chapel two miles out of Birmingham. After having filled the situation of assistant-master for about four years, he was appointed second master of the school, which had three masters and two assistant-masters, and at the same time took priest's orders. This mastership was only the seventh year of his life. He determined to give assistance to two brothers who had got into difficulties. 'In the good offices which he did them at the time,' says the biographer who has been already quoted, 'he so far showed his affection for them as to perform the deed with a due regard to his own welfare, as he was then circumstances.'

In August 1888, the poor schoolmaster suddenly fell ill at the house of a friend, and died of a second for he was the head of his own branch of the Wollaston family. Mr. Wollaston of Shenton, in Leicestershire, who greatly to his own surprise made himself heir. This gentleman had lost before his death lost his only son, and not choosing to go his estate to his daughter and his nephew and father of the subject of this sketch. But a further acquaintance with his younger relative, and the high character which he heard of him, led him before his death to revoke this settlement and make another. His cousin Nicholas, a gentleman of Shenton, who had been to our author's behaviour, who little suspected any such matter. And his behaviour was found to be such that the stricter the observations were upon it, the more they turned to his advantage. In fine, Mr. Wollaston became a lord mayor of the city of Birmingham, or Nicholas Charlton, a citizen of London, who brought another accession of fortune. He now devoted his mind entirely to the enjoyment of domestic happiness and the pursuit of learning. 'He may truly be said to have been his bishop's benefit of 28h. a year. He seldom went out of it. He took no delight in unoccupied journeys, and for above thirty years before his death he had not been absent from his habitation in Charter House Square so much as one whole night.' (p. xiv.) His studies were principally devoted to the antient languages, theology, and embraced mathematics and natural philosophy, and the Arabic language. In 1690 he published a paraphrase of a part of the 'Book of Ecclesiastes,' and in 1691 he composed and printed, but only for private circulation, a small Latin grammar. This ''Grammar Deb'nt' was published in 1724, but a very short time before his death. A number of other works, which he had written during his four-and-thirty years' studious residence in London, were committed by him to the flames before his death. Some of his manuscripts were destroyed, but others found escape the same fate only by the being forgotten:—1, A Hebrew Grammar; 2, Lyons Arabic et Syriaca; 3, Specimen Vocabularium Biblii Hebræici, litteris nostrabilibus; 4, Linguarum Semiticarum, &c.; 7, Formulae quadam Germaniae; 6, De Generibus Pudum, Meteorum, Carminum, &c.; 8, Judentos, Graecos, et Latinos; 9, De Vocabulis Arabico et Tyroso, adTyriam: Cursus Linguae Arabicae spectante; 10, Miscellanea Philologica; 11, Opus posthumum, Antiquitates et Particularia in the History of Man, and (12), all that had been lost upon this Earth from Eternity, &c.; 12, Some Passages relating to the History of Christ, collected out of the Patriotic Fathers; 13, A Treatise relating to the Jews, their Antiquities, Language, &c.; Besides this there was a numerous collection of manuscripts which have not been burnt but have been preserved above this Earth from Eternity.'
sketches of what afterwards reconsidered and carried on much farther, and which soon after such revival he nevertheless committed to the flames, as being still, in his opinion, short of that perfection to which he desired and had intended to bring them. (p. xxiii.)

Wollaston died on the 29th of October, 1724, in his sixty-sixth year. The immediate cause of his death was a fracture of the arm, which happened when he was in a state of health. His wife had died four years before. He had lived most happily together thirty years, and she had borne him eleven children, of whom seven survived their father. He was buried by the side of his wife in the church of Great Finborough in Suffolk, where one of his estates lay, and where his eldest son afterwards resided.

'The Religion of Nature Delineated' is, as the name implies, an exposition of man's various moral duties and the principles of them, independently of revelation, and of so much as may be learnt without revelation of the divine government of the world. (pp. 1-12)

Wollaston's system of morals is that he refers all duties to truth as their fundamental principle, defining truth to be the expression of things as they are, and extending the definition by the remark that 'a true proposition may be denied, or things may be possible that are by deeds as well as by express words, or another proposition.' As an instance, theft would be interpreted by Wollaston as a denial of the true owner's property in the goods stolen. On this somewhat fanciful foundation the whole range of human duties is extended. Former reasons, however, being revealed, is religion, is built up by Wollaston with great ingenuity and skill. The work is not complete: the author sets out with proposing to himself three questions to be answered: 1. 'Is there any thing in God, and religion, proper to the true Christian?' 2. 'If there is, is it?' and 3. 'How may a man qualify himself, so as to be able to judge for himself, of the other religions professed in the world; to settle his own opinions in disputable matters; and to engage in controversies of the highest sort of mind, without disturbing others, nor being disturbed at what passes among them?' Only the first two of these three questions are answered. Wollaston had begun to answer the third question, but had made little progress, when death overtook him.

The work was very popular on its first publication; ten thousand copies of it, according to Dr. Clarke, having been sold in a very few years. The best edition is the seventh last, to which is prefixed the biographical sketches, by Dr. Clarke, of Wollaston's various discoveries, of his life and works, and which was edited by him at the request, as he states in an advertisement, of Caroline, the wife of George II.

WOLLASTON, WILLIAM HYDE, M.D., a distinguished cultivator of natural science, was born August 6th, 1766, at London, in the county of Middlesex. He was the son of William Wollaston, of Chiseldon, in Kent, who from his own observations made an extensive catalogue of the northern circum-polar stars, which, with an account of the instruments employed and tables for the reductions, was published under the name of the world. (pp. 103-105)

Having gone through the usual preparatory course of education, he was sent to Caius College, Cambridge, where he applied himself diligently to the studies immediately relating to the medical profession, for which he was intended, and took the degree of A.B. in 1786: in the same year he was elected a Fellow of the Royal Society, to whose Transactions, during his life, he contributed many papers of the highest importance, and in 1805 he was chosen one of its secretaries. He was also appointed one of the vice-presidents of the Geological Society.

Dr. Wollaston entered into practice as a physician, and for a time resided at Bury St. Edmunds: he afterwards removed to London, and it might have been supposed that the New Year's Humours, in 1789, injured his health, and his reputation; but either because his success was not equal to his expectations, or in consequence of the disappointment which he felt in not obtaining the post of physician to St. George's Hospital, Dr. Pemberton having been preferred to him, he determined to quit the profession, and devote himself wholly to the pursuit of natural philosophy.

The researches of men of science, however important they may have been to mankind, by the improvements to which they have led in arts and manufactures, have seldom been productive of immediate benefit to those who first conducted them: some more fortunate person, by seizing on an original idea already propounded, and bringing it to the level of a practical application, may acquire both fame and fortune; while the original discoverer has remained unnoticed, and perhaps even his name has been forgotten. This was not the fate of Dr. Wollaston, in whom were combined the genius of the philosopher and the skill of the artist; since from his different discoveries, and particularly from that of a method of manufacturing platinum, he is said to have acquired a considerable fortune. No one however could have better deserved the rewards due to genius and industry; for not only were this the quintessence of his work, but his application to philosophical investigations and experiments was unremitting: even when near his last moments, though suffering under a painful malady, he had the fortitude to dictate an account of his most recent discoveries, and of multiples, in a paper 'On Super-acid and Sub-acid Salts,' printed in the 'Philosophical Transactions' for the year 1808: he now showed the important practical application of which this new metallic alloy, and by connecting the scale of equivalents with Gunter's sliding rule, has put into the hands of the chemist an instrument of the most valuable and essential in its uses, and equally essential to the student, the adept, and the manufacturer.

Mr. Wollaston's most noted contribution to the 'Transactions of the Royal Society' was in June, 1797, being an essay 'On Gouty and Urinary Concretions,' in which he made known several new compounds connected with the production of those maladies, in addition to the urine combinations previously known: these were—ammonium-acid carbonate of lime; ammonium-magnesia phosphate, a mixture of the two forming the fusible calculus; oxalate of lime; and more lately he added cystic oxide to the list of his previous discoveries. (Phil. Trans., 1810.) In 1804 and following years a new metal tincture was described, containing the metals contained in the ore of platinum, and associated with osmium and iridium, discovered about the same time by Mr. Tennant. In 1809 he showed that the supposed new metal tantalum was identical with columbium, previously discovered by Dr. Humphry Davy. (Phil. Trans., 1809.) In 1810 he showed to the Royal Society the Bakerian lecture, in which he fully describes his ingenious method of rendering platinum malleable. (Manual of Chemistry, p. 108.)

His 'History of Chemistry' (vol. ii., p. 248) Dr. Thomson remarks:—Dr. Wollaston had a particular turn for contriving pieces of apparatus for scientific purposes. His reflective goniometer was a most valuable present to mineralogists, and it is by its means that crystallography has acquired the great degree of perfection which it has recently exhibited. He contrived a very simple apparatus for ascertaining the power of various bodies to refract light. His camera lucida furnished those who were ignorant of drawing with a convenient method of obtaining exact and parallel lines, those sitting out of his way.
of galvanism and common electricity; and the first explanation of the cause of the different phenomena exhibited by galvanism and common electricity.

Without entering further into an account of the various papers by Dr. Wollaston which appear in the 'Philosophical Transactions,' we shall conclude with the following general remarks on his scientific character, by a professed judge of its excellence, the late Dr. Henry. Dr. Wollaston,' he observes, 'was endowed with bodily senses of extraordinary acuteness and accuracy, and with great general vigour of understanding. Trained in the discipline of the experimental sciences, he had acquired a powerful command over his attention, and had habituated himself to the most rigid correctness, both in thought and language. He was sufficiently provided with the resources of mathematics to be enabled to pursue with success profound inquiries in mechanical and optical philosophy, the results of which enabled him to unfold the causes of phenomena not before understood, and to enrich the arts connected with those sciences by the invention of ingenious and valuable instruments. In chemistry he was distinguished by the extreme nicety and delicacy of his observations, by the quickness and precision with which he marked resemblances and discriminated differences, the sagacity with which he devised experiments and anticipated their results, and the skill with which he executed the analysis of the fragments of the results; so often so many of his experiments were cleared every step of his ascent a secure station, from which it was easy to rise to higher and more enlarged inductions.'

WOLSTONEONITE. TUBULAR SPAR. SILICATE OF LIME.

Lustre vitreous. Translucent. Transparent. Specific gravity 2.14. Amorphous. The commonest form of colurnbar crystals lying in all directions, or fibrous, the fibres being either parallel or divergent.

Before the blow-pipe on charcoal, the edges are melted into a semi-transparent colourless glass; but it requires a very great heat to fuse it perfectly; with which it readily melts in large quantity into a transparent glass.

It is found in very perfect crystals at Vesuvius, at Cape di Bove near Rome, in the Bannat, Ceylon, North America, Sweden, &c.

It has been imperfectly analysed, and from various places with but little difference in the results; No. 1 is the analysis of a specimen from Calklows in the Bannat, by Stromeyer, and No. 2 of a specimen from Parges in Sweden, by Bonsdorff.

WOLLIN is an island at the mouth of the Oder, and forms part of the circle of Usedom and Wollin, in the province of Pomerania. It is situated in the mouth of the Frische Haff, the rivers Swine and Divenow, and the Baltic. It is nearly 100 square miles in extent, and the population is 6000. It is well wooded, and has good pastures. Pritzer, a village near the Swine, is celebrated for its hemp, which greatly improves the hemp of the place, and for the fisheries and the timber trade. They also manufacture some coarse stuffs. The town is connected with the continent by three bridges over the three arms of the Divenow. Here, or in the immediate vicinity, stood the town of Julin, which was a populous place, the entrepôt of the Baltic trade, but which was totally destroyed by Waldemar, king of Denmark, in 1170.

(Hassel, Handbuch; Müller, 'Wörterbuch des Preussischen Staates'; Hübner's Zeitungs-Lexicon; Stein's Lexicon.)

WOLLSTONECRAFT, MARY. (Godwin.)

WOLSEY, THOMAS, the celebrated cardinal of that name, was born at Ipswich in the county of Suffolk, in 1471. The tale that he was the son of a butcher is incredible, though it does not rest upon any sure foundation. It appears that Robert and Joan Wolsey, his parents, were poor but reputable persons, and possessed of sufficient means to provide a good education for their son. After having sent him to a school in Connecticut, he was admitted to Magdalen College in Oxford; where he graduated at the age of fifteen, gaining by his early advancement the nickname of the boy bachelor. (Cavendish's 'Life of Wolsey.')

He was made fellow of his college, appointed tutor's school in connexion with it, and was ordained. At school were three sons of the marquis of Dorset, with whom Wolsey became acquainted, and through whose patronage Wolsey enjoyed his first ecclesiastical preferment, the living of Lymington in Somersetshire. He was otherwise. An estate of three and a quarter in the address, which, combined with great natural ability, and a keen and rapid judgment of character, greatly assisted his promotion. We cannot follow him through every step of his progress, even at the beginning of his career. Thence we know that he was in time appointed chaplain at Exeter, received friendships and obtained confidence in each place where he resided. It is said that while he lived at Lymington he got drunk at a neighbouring fair; for some such reason it cannot be, he lost some of his red tape, a punishment for which we find that he subsequently resented himself. Still he had wherewithal to counterbalance his errors. Through his intimacy with a Somerset gentleman of some importance, he shortly afterwards obtained two appointments. The first was to Pdden with a message concerning the marriage of the king; dispatch was necessary, and the king intrusted the business to Wolsey, who travelled with such rapidity as to return to London before his master knew of his departure. He was thereby raised to a position above the rest of his order; was summoned to parliament to answer for his conduct, was nominated Archbishop of Canterbury, 1508. In the following year the king died, and a second cardinal Wolsey, widely different from his father's, raised a general expectation of an entire change of counsellors and favourites.

Up to this time Wolsey had had no opportunity of playing a great part. He had risen indeed, and very rapidly; but he was an object of low birth, and sufficient time had not elapsed for him to gain any very great elevation. But in the changes to be made in the accession of the new king, it soon became evident that Wolsey's position was such as to give the king great satisfaction: the credit that he raised by this service contributed to procure him the valuable deanery of Lincoln, to which he was appointed in February, 1508. In the following year he was created cardinal, and, as a second cardinal, was raised to the archbishopric of York. This was a matter of great public interest, and no wonder the people contributed to secure him a place near the person of the king. There were animosities between the earl of Surrey, the lord-treasurer, and Fox, bishop of Winchester, who held the important offices of privy seal and secretaries of state. The king, therefore, sought to place near the king one of his own friends and adherent. For this purpose he made Wolsey the king's almoner, trusting that his active spirit, his acuteness, and infatuated address would make the favourites of the court, the chief encroachments of the bishop's domain, and the chief courtier did not disappoint his patron: he rose so quickly in the king's good graces, that he soon did nearly what he pleased. He had no religious scruples to deter him from accepting
the king's humours and pleasures; on the contrary, he pro-
moted his careless gaiety, knowing well that the more time
the clergy employed in its pursuit, the more necessity
he should find to use his wiles to conciliate him with
the information which he needed, and to proceed with the busi-
ness which he intended to transact. Thus, though the king
never wholly neglected his affairs, the conduct of them chiefly
fell to Wolsey's share. The success of his
general management was soon proved by the gifts that
were bestowed upon him. Before the year of the king's
accession had passed he had been made lord-almighty, and
had been presented with some valuable lands and houses in
the See of St. Paul's. The archbishopric of York was never
held forfeited to the crown. In 1510 he became rector
of Torrington; in 1511, canon of Windsor and registrar
of the order of the Garter; in 1512, prebendary of York;
in 1513, dean of York, and bishop of Tournai in France; in
1514, bishop of Lincoln, and in the descent year Adrian VI.
of York. In 1516 he was made a cardinal, and succeeded
Warham as chancellor. In 1516 the pope made him
legate a latere, a commission which gave him great wealth,
and almost unlimited power besides. Yet he,
likewise, married for the foreign bishops who held them, the
revenues of the dioceses of Bath, Worcester, and Hereford,
allowing them fixed stipends far below the annual pro-
ceeds which were collected; he had also in commendam
to the queen Catherine, his last wife, a sum of money
that he derived from these sources were further increased
by stipends received from the kings of France and Spain
and the duchy of Venice. Thus Wolsey had the whole
power in the state, both civil and ecclesiastical, and derived
from his exactions both against the foreign excommunicated
which no subject has ever approached: his wealth and
influence were almost an encroachment on the dignity of
the crown. His ambition however was not satisfied;
his anxiety for the papacy was avowed; nor did his expecta-
tion of greater wealth. He sought the marriage of Maximilian (1519) both the kings of France and Spain
aspired to the empire; and each, eager to secure the
influence of so powerful a minister as Wolsey, promised to
assist him in his designs. At the death of Leo X. in 1522,
remaining in England, the marriage of Anne of Cleves,
Wolsey sought the vacant throne, but in neither instance
was he chosen. His foreign policy seems to have been
biased by his disappointment, which he attributed to
Charles V., whom he ever afterwards held in aversion.
We have other instances of the continuance of his resent-
ment and his inability to forgive. He had taken offence
at the duke of Buckingham's conduct towards him: that
nobleman's indiscretions afterwards subjected him to an
attack on the dignity of the court, which was increased by
severity; and though there were no public reasons for such
harshness, instigated his execution. An outcry was raised
against him for his want of leniency towards this popular
favourite; it soon subsided however, for his power made
him a great influence admired.

Nobody could vie with Wolsey in display: his retinue on
the Field of the Cloth of Gold was more numerous and
splendid than that of any subject; and during each foreign
mission on which he was employed, he was attended with
extraordinary pomp. At York Place (now Whitehall), his
residence was furnished with every luxury; and he built
for himself at Hampton Court a noble palace, of which he
eventually made a present to the king. His dress was
gorgeous, his habits as sumptuous as his dress; he had
command of more than fifty human beings; there
were among them many people of rank, the earl of Derby,
Lord Henry Percy, and others. He had 'a steward' (says
his biographer Cavendish, who was his gentleman-usher)
'who managed and conducted all his servants; a steward,
and a comptroller an esquire; which have always
within his house their white staves.' In his privy kitchen
he had a master-cook, who went daily in damask, satin, or
velvet, with a chain of gold about his neck. The
provisions which were used however were by no means such
though it must be added that he promoted learning with
consistent liberality: the university of Oxford is indebted
to him for its Cardinals, now Christ Church College; and
for several professorships, which, with the lectures,
found him a very liberal patron. He was the father of Ipswich, but not only had
short absence: he likewise encouraged learned persons by
patronage and gifts. He was himself no mean scholar, and he is said to have assisted the king, by his intimate
knowledge of the works of his favourite author, Thomas
Aquinas, and other theological writers, when he composed
his treatise against the Jewish writers. He had,
in the Latin rules for his school of Ipswich, which are extant:
they are printed in the 'Essay on a System of Classical
Instruction' (London, John Taylor, 1825), and contain
the course of Latin instruction which Wolsey prescribed for
the Athenian boys into which he divided the school.

The see of Durham, to which he had been recently ap-
pointed, Wolsey resigned for that of Winchester. It does not appear that he encouraged any change of doctrine
among his clergy: his adherence to the Roman Catholic
Church was unchangeable. The Reformation, however,
made little progress, though many of its seeds were sown in his
time. His abuse of ecclesiastical revenues and duties
gave convincing evidence of the necessity of change: such
rapid translation from dignity to dignity, so large a number
of offices held continually by the same hand while their
duties were for the most part neglected, were evils that
could not long be tolerated. The exercise of his legislative
powers with regard to the examination and suppression of
the monasteries, his conduct likewise in the matter of
Queen Catherine's divorce, gave strength to the dawning
Reformation.

To circumstances connected with the divorce Wolsey's
fall is mainly attributable: he advised the king to put
his resolve against his wife; he offended both the actual queen and the queen elect.
An oppressive and illegal taxation had made him unpo-
pular with the multitude; while at court there were pow-
erful enemies labouring continually to poison the king's
judgement against him. A certain prebendary, whom he had treated with such
unlimited confidence, and trusted with such unparalleled
authority. The dukes of Norfolk and Suffolk, and Lord
Rochford, Anne Boleyn's father, united in their efforts to
overthrew him. 'They insinuated,' says Dr. Lingard, 'that
he had never been in earnest in the matter of the dis-

vorce, and had uniformly sacrificed the interests of his
sovereign to those of the king of France.' At length Anne
Boleyn induced the king to promise that he would speak
to him no more. At the commencement of the Michaelmas
term, 1529, twenty side-churches were suppressed in the
Court of King's Bench, charging him with having, as
legate, transgressed the statute of primogeniture. Wolsey
admitted the charge; 'of which he was technically guilty, inasmuch as he had received the pope without
normal licence.' (Sir J. Mackintosh, 'Hist. Eng.,' vol. ii.,
p. 166.) 'The court pronounced their sentence, that he
was out of the protection of the law, that his lands, goods,
and chattels were forfeited, and that his person was at the
termination of the court in the county-house belonging to the see of Winchester; and
was so closely shorn of all magnificence, as nearly to be
wanting in the ordinary comforts of life. Many of his
friends deserted him: Johnson's celebrated words ('Vanity
of Human Wishes')—

Mark the keen glance and watch the sign to late,
Where'er he turns, he meets a stranger's eye,
His suppliants soon him, and his followers fly—

are true, save in their reference to his followers, who showed most flattering attachment to his master in his
distress. He sank into a state of the most abject dejection
(Lingard, vol. vi., p. 209), until even his enemies could
not help pitying him. His capacious master temporarily
restored to the see of Winchester and the abbey of St.
Albans, with a grant of 6000l., and of all other rents not
parcel of the archbishopric of York. Even that great
diocese was afterwards restored. He arrived at Cawood
Castle about the end of September, where he em-
ployed himself in magnificent preparations for his installa-
tion on the archiepiscopal throne.' His popularity in
the north was increased by his hospitality and an affability
which circumstances had taught him. If enemies at
first hesitated to cast off the pope favoured their design,
for under these circumstances it was evidently little desirable
that a cardinal should fill the principal offices in the
Church. The earl of Shrewsbury and his friends
arrested him for treason, and brought him to London to stand
his trial. With what particular act he was charged we are
not informed. He proceeded towards London on his
mule, but by the way he was attacked with a dysentery.
As he entered the gate of the monastery at Leicester, he said, 'Father Abbot, I come to lay my bones among you;' and so the event proved: the monks carried him to his bed, upon which, three days afterwards, he expired (November, 1530). Shakespeare has little altered the words he used on his deathbed, though they were spoken to Kyngton, the lieutenant of the Tower, and not, as in the play, to Cromwell:—

'Had I but served my God with half the soul / That served my lord, he would not now lie here / With thick unburied earth upon his bones.' Henry VIII., Act iii., sc. 2.

'The king,' says Hume, 'much regretted his death, and always spoke favourably of his memory: a proof that human nature in its reason or any discovery of the hand of Providence had occasioned the last persecutions against him.'

Wolsey attained his elevation by a winning address, combined with shrewdness, talent, and learning; his ambition and capacity were unlimited; he was revengeful, arrogant, and clever-ranging. An extreme fondness of display and parade. There can be no doubt that he used his influence abroad as well as at home for his own advancement; but upon the whole he was a valuable minister, enlightened beyond the age in which he lived, diligent in business, and a good servant to the king for whose authority he was established he restrained many of the king's caprices, and kept his passions within bounds: the latter part of Henry's reign was far more criminal than that during which the Cardinal governed over his own house. His part in the death of the duke of Buckingham,' says Sir J. Mackintosh, 'was his most conspicuous crime: the circumstance most favourable to him is the attachment of dependants.'

For the rest the standard of morality was but low, and there was little in Wolsey's character which tended to raise it. Had there been a doubt that Thomas Winter was his natural son, it would have been almost removed by his confessing eleven benefices upon him. He is said to have had two other children, but the fact is not accurately proved.

(Cavendish, Life of Wolsey; his Life, by Fiddes; Grove, Life and Times of Wolsey; more modern Lives, by Galt, in Lardner's Cyclopædia, and in the Lives of Eminent Persons, by the United Knowledge Society; Hume's and Lingard's Histories.)

WOLSEY'SHAM. [DERBY,]

WOLVERHAMPTON, a large manufacturing town and parliamentary borough in Staffordshire, 126 miles north-west of London by the Birmingham and London railway, and about 13 miles north-west from Birmingham.

Wolverhampton is situated on rising ground, and consists in general of substantial and well-built houses, mostly of brick; the streets are somewhat irregularly laid out, and not bordered, but are well-tended, there is a neat theatre and a public subscription library, over which is a suite of rooms used for concerts and assemblies. There are four churches; the oldest is that of St. Peter, a spacious structure, capable of accommodating 1000 persons. The pulpit is great, and is uniformly sculptured, and there is a font of great antiquity, with curious bas-relief figures of saints. In the churchyard is a column twenty feet high, with rude sculptures in compartments, supposed to be of Saxian or Danish workmanship. The church is collegiate, and the dean, who holds the prebend of Wolverhampton, and seven other prebendaries, by a grant of Edw. IV., confirmed by subsequent grants, the deanery and prebend of Wolverhampton, being annexed to the deanery of his free church of St. George, within the castle of Windsor. The net revenue, on an average of three years ending 1831, is £461.

The dean receives the whole revenue. The living is a perpetual curacy, in the patronage of the dean of Windsor, and of the average net annual value of £307. The other churches are modern, and all perpetual curacies: St. John's, in the patronage of the Earl of Stamford and Warrington, of the net annual value of £203; St. George's, in the patronage of the dean of Windsor, of the net annual value of £326; and St. Paul's, of which the value is not given in the Report on Ecclesiastical Revenues. All the chief denominations of dissenters have places of worship. A dispensary was established in 1821, and the present commodious building was erected in 1830. A union-mill was built in 1813, at an expense of 14,000l., for the purpose of grinding grain at a cheap rate for the poor. We have authors which state whether it continues to be used for that purpose. There is now a union workhouse, which, in 1841, contained 204 persons.

According to the Education Returns of 1833, there were four infant schools and fifteen daily schools. Of the daily-schools, one was a free grammar-school, supported by endowment, with 70 male scholars; the salary of the head master was 400l. of the second master, 200l. and of the assistant master, 120l. This school, supported partly by endowment and partly by subscription, which, in 1833, educated 100 male scholars and 50 female scholars. There was at the same date a national school, with 400 children of both sexes daily and 240 on Sunday. Besides these, there were two board-schools or three or four Sunday-schools supported by different classes of dissenters.

Wolverhampton was made a parliamentary borough by the Reform Act, and returns two members to parliament. The population of the town is 87,508 in 1841. There are 906, 1,183, 1831, 70,780 in 1841 it was 70,780.

The district in which Wolverhampton is situated abounds in mines of coal, iron, limestone, and other minerals, at the manufactures consist chiefly of iron-works, and iron-ware, locks and keys, guns, firearms, and a variety of other articles of hardware. Besides its way-communication with London, Birmingham, Liverpool, Manchester, and other towns on the same line, it is connected by canal-navigation with most of the great towns of England—London, Hull, Birmingham, Derby, Notts, Chester, Liverpool, &c.

A monastery was founded at Wolverhampton in 694 by Wulfrans, sister of King Edgar. The monastery was surrendered to Hubert, archbishop of Canterbury, in 1217, and the lands afterwards annexed the bishopric of Windsor. The town was named Wulfruna Hama, after the foundress of the monastery, which by contact and corruption has become Wolverhampton.

(Boundary Reports, 1832; Education Enquiry, on Educational Revenues of England and Wales: Population Returns.)

WOLVERINE. [GULO.]

WOMAN. [MAN.]

WOMB. [MACHUPILLA, vol. iv., p. 489.]
The secrets of plants that are most important to man are not often deposited with woody tissue, and therefore the wood of trees is not often employed as food or medicine. Animals however are found capable of digesting the lignine of which woody tissue is composed, and thus wood forms a part of the diet of some forests, and for man himself lignine may be treated chemically in such a way as to render it a nutritious article of diet. It is the peculiar resinous, gummy, oily, or other secretions, that give to the various woods their different colour, smell, and taste. The following matter is sometimes deposited on such abundance as to render it useful for dyeing, as seen in logwood, red sanders-wood, and other woods used as dyes. Some woods have volatile oils deposited in them, which, being constantly given out, renders them odorous; and this is the case with sandal-wood, rose-wood, the wood of cedar, fir, and other trees. Frequently bitter and other secretions are deposited in wood, giving it a peculiar taste, and rendering it useful in medicine. The wood of this quassia, as well as of the same species, is employed for the tanning of hides.

If wood is submitted to destructive distillation, it is decomposed, and the consequence is the production of acetic acid and an oil, which is then removed, and the leaving a certain quantity of charcoal. The following is the table of the products of the distillation of one pound of different woods dried at 86° Fahrenheit:

<table>

</table>

The woods that are used by the cabinet-maker for furniture of a more delicate kind are called fancy-woods. The use of these has become much more general since the introduction of the art of veneering; and now that this is done by machinery instead of hand, a number of woods are used for furniture and other purposes, which, on account of their scarcity, could have been formerly used only to a very limited extent. [VENNERING; SAW-MILL.]

The most common of the fancy woods and that which is used most by the cabinet-maker is mahogany. This wood is the produce of the Sterculia mahogoni. [SWITZENVIA.]

Next in point of importance and use to mahogany is the Rose-wood. This wood obtains its name from its fragrance, and is the produce of a mimos from the coast of Brazil. In veneering it affords from eight plates to the inch. King-rose is a beautiful wood much in use; it is brought from Brazil in logs four feet long and about five inches wide. It is used only for delicate articles, and is said to be the produce of a species of Baphia, a genus of leguminous plants. Rose-wood is a very hard wood, of a pale red colour, and is brought from New Holland in logs nine

The conducting power of wood in relation to heat is a matter of importance in the construction of buildings and other purposes. In some experiments performed by Delaive and De Candolle on prisms of different kinds of wood, to ascertain their power of conducting heat, they found that the direction of the fibres materially interfered with their conducting power. Thus it appeared that the obstruction of the passage of caloric was greater when the current was at right angles to the woody fibre than when it flowed longitudinally in the direction of the fibres. This difference also appeared to increase in proportion as the wood was a bad conductor of heat. The conducting powers in the two directions may be represented very clearly by the following numbers:

<table>
<thead>
<tr>
<th>Length of the fibre</th>
<th>Conducting power.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nut-wood</td>
<td>5</td>
</tr>
<tr>
<td>Oak</td>
<td>5</td>
</tr>
<tr>
<td>Fir</td>
<td>5</td>
</tr>
</tbody>
</table>

Hutchinson found in his researches on the conducting power for heat of building materials, that taking the conducting power of fir-wood as 100, beech-wood was 83·10, and oak 134·10. But if the woods were compared with slate as 100, their conducting power would be as follows:

<table>
<thead>
<tr>
<th>Conducring power.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fir-wood</td>
</tr>
<tr>
<td>Oak-wood</td>
</tr>
<tr>
<td>Beech-wood</td>
</tr>
</tbody>
</table>

The cooling power of these woods is another important point, and this is not at all in relation to their conducting power: thus fir-wood being 100, the cooling power of oak-wood is only 30·38, whilst that of beech-wood is 120·2. Compared with slate as 100, the cooling power of the woods are as follows:

<table>
<thead>
<tr>
<th>Cooling power.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oak-wood</td>
</tr>
<tr>
<td>Fir-wood</td>
</tr>
<tr>
<td>Beech-wood</td>
</tr>
</tbody>
</table>

Another important point of inquiry with regard to the physical properties of wood, as to its value in building, &c., is its relation to moisture. If the specific gravity is 1·000, we should expect that the less the specific gravity of the wood the greater would be its capacity for moisture; and Hutchinson found, on immersing 100 grains of each of the following woods for twenty minutes in water, that such was the result, for they had gained as follows:

<table>
<thead>
<tr>
<th>Gained.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oak-wood</td>
</tr>
<tr>
<td>Fir-wood</td>
</tr>
<tr>
<td>Beech-wood</td>
</tr>
</tbody>
</table>

The wood that is most used by the cabinet-maker for the manufacture of veneer, or that is most resembling mahogany, is the Rose-wood. This wood obtains its name from its fragrance, and is the produce of a mimos from the coast of Brazil. In veneering it affords from eight plates to the inch. King-rose is a beautiful wood much in use; it is brought from Brazil in logs four feet long and about five inches wide. It is used only for delicate articles, and is said to be the produce of a species of Baphia, a genus of leguminous plants. Rose-wood is a very hard wood, of a pale red colour, and is brought from New Holland in logs nine
foot long and thirteen or fourteen inches wide. The tree from which this is obtained is unknown to botanists. The wood is literally that which is used for making the fancy-woods of commerce. Tulip-wood is brought into the market in very small pieces, not more than four feet long and five inches in diameter, so that probably it is the production of a shrub. It is clouded with red specks, which give it a yellow colour and are used for bordering and making small articles, such as caddies and work-boxes. Zebra-wood is the production of probably a large tree, as it is cheap enough to be made into tables, pianofortes, &c. It is coloured brown on a white ground, and clouded with yellow streaks. Tronc-wood is a brilliant yellow wood, with delicate glowing shades. It is the produce of a plant called Chlorosygon Sieberiana, and is a native of India. It is one of the trees that yield the wood-oil of India, and it belongs to the natural order Caudalaceae, the same order in which the mahogany is placed. It is found in the market in logs two feet wide and seven or eight feet long. Sandle-wood is the produce of a species of Sandoricum belonging to the family Meliaceae. The wood is of a light brown colour, with golden-coloured veins. Ebony-wood are the names given to some very hard woods, the produce of the natural order Ebenaceae. These woods are mostly brought from India, although some of the species are found in Europe and America. There are several other woods occasionally used among cabinet-makers and work-masters, and of which little is known, either as regards to the places they come from or the trees to which they belong. Canopy-wood has a deep yellow colour; Purple-wood has a purple colour, without veins; Siam-wood is of a dark brown colour, with yellow shades; Calamander-wood is a handsome, cheap wood, taking a high polish, and is brought from Ceylon. Other woods are called from the places they come from, as Coromandel wood, Ambonya wood, &c.

The practice of staining wood is sometimes had recourse to for the purpose of making the more common woods resemble in colour the fancy-woods. A method has lately been proposed of doing this by introducing into the tree during its growth various colouring agents, so that during the process of drying the natural colour of the wood is taken up and deposited in the woody tissue. Some of the woods thus treated have been made to assume very remarkable colours, but as the trees on which it can be practised are too soft and coarse for fine work, it is not likely that this method will at all supersede the use of the naturally beautiful fancy-woods.

For further information concerning wood consult the articles Exogenous; Endogenous; Lignin; Lignite; Vegetable Kingdom; Tissues; Vegetable for information concerning woods of particular names, see the name of the genus, as elm, Ulmus; oak, Quercus, &c.: for laws relating to wood, see Timber and Timber-trade.

W O O D, or A W O O D, ANTHONY, was born in the city of Oxford, Dec. 17, 1632. His father was a gentleman of Eton College. Anthony was sent to a private Latin school in 1640, and in 1641 was removed to New College, Oxford, but in 1644, in consequence of the civil disturbances, was sent to a school at Thame. In 1647, he placed himself under his brother Edward at Trinity College, Oxford, and he went to him once or twice a day to receive instruction. On the 29th of May, 1647, he was matriculated in the University of Oxford as the son of a gentleman, and entered Merlon College, Oct. 18, 1647, and in 1648, aged 19, he began to learn to play the violin, at first without instruction, but afterwards under a teacher. He seems to have attained to great skill on the instrument, and was for many years a member of a musical club in Oxford, in which concerted pieces were performed, both at home and abroad. One of the ablest of some eminent church musicians. Painting was also another of his favourite pursuits, but there seems to be no evidence of his skill in that art. He graduated A.B. in 1652. Hereditary, which also became one of his studies, was perhaps better suited to his attainments than his musical studies. The University attracted the attention of Dr. Thomas Barlow, the head keeper of the library, who treated Anthony with much kindness, gave him every assistance in his power, and even allowed him to take books and manuscripts to his home.

In December, 1655, Wood took the degree of A.M. Dugdale's 'Antiques of Warwickshire' came out in 1652, and was read by Wood with great delight and admiration. His fondness for the study of antiquities was confirmed on his removal into the muniments and arms in the parish churches and colleges church of the city and university of Oxford. After the restoration he obtained leave from Dr. Wallis, in 1660, to copy the University registers, monuments, and other documents in the Sheldon Tower. This was a valuable fund for his future study, and here he may be said to have laid the foundation of his History and Antiquities of Oxford.' In 1667 Wood went to London with a letter of introduction from Dr. Rolle to Sir William Dugdale, by whose influence he obtained leave to peruse the manuscripts in the Cotton Library and the records in the Tower.

Wood having completed his History and Antiquities of Oxford,' the University offered him 100L for the copy, which he accepted in October, 1669, and the payment was made in 1670. This was with the intention of having the work translated into Latin for use of foreigners, which was done under the inspection of Dr. Fell, and the work was published at Oxford in 1654 in 2 vols. folio, with the title of 'Histoires antiquitates Oxonienses.' Of this translation, &c.; Dr. Thomas Worson, who says it is supposed to be a less prejudiced judge, remarks, 'I cannot omit the opportunity of mentioning that Dr. Fell's version is more correct in the sense of Wood, and that the English work is, I think, infinitely more pleasing in its style and diction, in its artless but accurate author. The translation in general is allowed to be full of mistakes: it is also of an unpleasing, perpetually disgusting the reader with an affected prosody.

In 1681 Wood published his 'Athenea Oxoniensis, an exact History of all the Writers and Bishops who have held their education in the University of Oxford from 1500 to 1685, to which are added the Fasti or Annals of the University from the year 1167, with a translation into English, written in very slovenly English, but it contains a valuable fund of materials, selected with care, though not always with judgment and without prejudice. He was prosecuted in the vice-chancellor's court of the University for some remarks in the same book, on the character of the late Earl of Clarendon, and received a sentence of expulsion. He was also tried by Bishop Burnet, and reprieved in a 'Vindication,' &c., in 1709.

Wood died Nov. 29, 1695, aged 65. He was a large strong man. He retained his faculties to the last, and just before he died gave directions for the burning of a great mass of manuscripts, and left his books and such of his manuscripts as he considered of value to the University of Oxford; they were deposited in the Ashmolean Museum. In 1721 a second edition, 'corrected, and enlarged with the addition of above 500 new lives from the authors original manuscripts,' was published in London, 2 vols. by Philip Bliss, and published at Oxford. Wood's Athenae Oxonienses continued to 1800, 4to. 2 vols., 1818. In the 7th volume, published in 1717, was added 'Fanti Oxoniam or Annals of the said University, with Notes and Additions.'

The Rev. John Guth, M.A., register of the University of Oxford, published in 1788-94, at Oxford, 'The History and Antiquities of the University of Oxford, now first published in English from the original manuscripts in the Bodley Library in the University of Oxford.' The book was published to the present time, by the Editor, 3 vols. 4to. (Biographia Britannica; Watt's Bibliotheca Britannica.)

W O O D, JOHN, commonly spoken of as 'Wood of Bath,' was an architect of considerable reputation, and in the time of George II., in ability and taste little if at all inferior to any of his contemporaries; although he has obtained less notice from architectural and biographical writers than some of them have done. In fact, he little can now be traced in the polite library, unless by himself what he has himself incidentally told us in his 'Description of Bath. That city is indebted to him for its architectural plan, and he may be considered as having introduced a style

WOODY

about architecture till then quite unknown in this country, by combining a number of private houses into one general design; and although such mode of producing continuous facades was afterwards adopted by the Adamas, it was followed by Nash, and has since become very general. Wood stated his methods to be nearly the first in point of time at the end of the 16th century.

It was about the end of 1736 that he began his Bath improvements, which he carried on uninterrupted for about twenty years, within which time he entirely changed the place. They do complete the surrounding scenery upon even a degree of magnificence, at least as displayed in such parts as the Parade, the Circus, the Royal Crescent, Queen Square, and some of the public edifices, and none of these would have been superior to what they are now, if Bath were designed by any other architect. If not altogether proof against criticism, they are at any rate free from the sneering reproaches levelled against many later works of the kind, as being mere bath and plaster; and Smollett has spoken of them very depreciatingly in his novel of "Humphrey Clinker," others have been even more prodigious of praise. Among last is the author of the "Principles of Design in Architecture," Theodor, who says, 'With all its faults in parts, I must reckon the Crescent at Bath among the most extensive, the most noble, and the most entirely carried out, as the world, and he further lauds the large decay of architectural taste at Bath since Wood's time.

What he did at Bath alone would justly entitle him to rank in English architecture, and not least of all for the very reason which has perhaps accustomed him to be passed over with mere passing notice, namely, as he distinguished himself as the founder of a system of improvement that has never been equalled, and has never been surpassed in its true spirit and in its intention to produce some works of the latter class that would have preserved his name from oblivion, and among them as the noble mansion of Prior Park, erected for the person of Sir John Throckmorton. This house was finished in 1743. This last, if not a very large, a very noble structure (110 by 148 feet), and the principal would for a much greater extent of the Palladian style than anything by Palladio himself.

Wood, while engaged in the peace for Ireland, died May 23rd, 1754, but at what age is not said: he was probably born about the close of the 17th century. He was also known as a philosophical writer, and upon his life by his Origin and Character, which was published, more or less, 1741, which was afterwards enlarged and improved in its arguments, its opinion tending to show that the system of architectural beauty and proportion is derived from the Jewish nation. To this subject, whether they are entitled to a description of Bath, second edition, 2 vols. 8vo, plates, London, 1745; and 'Description of the Exchange of Bristol,' with plates, 8vo, Bath, 1745.

WOOD, HENRY, was an accomplished scholar and archæologist, a native of Ireland, having been born at Riverstown in the county of Meath, in 1716. Having finished his studies at Oxford, where he applied himself with extraordinary diligence to classical and more especially Grecian literature, he resided Italy more than most in 1726 made a voyage as far as the island of Chios; but it was not until 250 that, in conjunction with his friends Bouvierie and Avius, and with the Italian architect Borra for their labour, he set out on his celebrated antiquarian expedition through Italy. Before returning Palmyra, Bouvierie died of fatigues, but Wood and his remaining companions pressed their researches and labours with success. Almost immediately on his return he published his "Essay on the Genius of Homer," he was made under-secretary of state by the Earl of Chatham, in consequence of which he suspended his literary studies, and that work was not published till after his death (which happened at Putney, September 13, 1771), when it appeared under the title of 'An Essay on the Original Genius and Writings of Homer; with a Comparative View of the Ancient and Present State of the Trojans,' 4to, London, 1775. This learned dissertation, which has been translated into French, German, Italian, and Spanish, treats of the country of Homer, his travels, his system of mythology, and of the theory of poetry and ethics in his "Odyssey." It is however by his two other works that he is now more generally known, and they are a most important addition to the history and archæology of architecture, affording the most extended notice of Roman magnificence in distant regions, and in places where its existence had come to be nearly regarded as fabulous. For some account of the edifices there discovered, see BAILLIE AND PALMIRA.

WOODALL, JOHN, an English surgeon, was born about the year 1556. He was a surgeon in the army during the reign of Queen Elizabeth, and went to France with the troops under Lord Willoughby. On his return he settled in London, and was very active in his attentions to those sick of the plague which prevailed in London in the early part of the reign of James the First. There is no record of his having been a surgeon in the navy, but in 1612 he published a work describing the diseases of sailors. He was appointed to the title of the 'Surgeon-Major.' In this work there is an excellent account of the fearful epidemic, as it prevailed at that time, known by the name of scurvy. In the same year that he published this book he was appointed surgeon to St. Bartholomew's Hospital. In 1623 he published a work entitled "The Author's Practice, as a Treatise on the Plague," and a work upon "Gangrene and Spasmodicum." All these works were collected together and published in London, in 1639. These works display sound observation and correct reasoning, and obtained for him an extensive reputation. He had a large practice in London, and was made a master of the Surgeons' Company. There is no account of him at which he died. In the preface to the works published in 1639, he speaks of himself then as in infirm health. (Hutchinson's Modern Biographies.)

WOODBINE. [CONTULYCHAE.] WOODBRIDGE. [SUFFOLC.] WOOD-CUTTING MACHINERY. This term, though applicable also to contrivances for cutting wood by means of toothed instruments which tear away or remove a portion of its substance, and which are treated of under Saws, is, vol. xx., p. 476, and under Mill, p. 168. it is the same volume, as being too distinct a subject to be thus treated. It is for dividing wood by knife-like or sharp-edged instruments, which most commonly act by the simple division or separation of the fibres, as explained under Saw, and which are merely split off from the surface by intersecting its fibres, divide it into several pieces without any waste of material such as is necessarily occasioned by the use of a saw.

The valuable nature of some of the woods used for veneering, and the extreme thinness of the sheets into which it is divided, often not exceeding the thickness of the saws employed for cutting them, renders it important to save the wood which is reduced to sawdust and wasted by the ordinary method of cutting. This has been accomplished in some degree, by using the flat or horizontal veneer machine, acting upon the same principle as a carpenter's plane, but powerful enough to remove, by a single operation, a shaving thick enough to be used for veneering, and equal in width and length of strips, and divided into its fibres. This principle of cutting has been most ingeniously applied in a veneer-cutting machine used in Russia, of which descriptions have appeared in many English works on machinery. In this machine the length of the blade is rather less than the length of the log, which is to be converted into veneer, and the log is mounted upon an axis parallel with its edge, and turned to a circular form. The blade is then pressed against the log in such a way that, as the latter revolves slowly upon its axis, a thin spiral sheet or shaving is cut from its surface, and as the former is pressed in proportion to the constantly diminishing diameter of the log, this operation is continued until the greater part of the timber is converted into one continuous sheet of veneer, which, as fast as it is pared off, is rolled up upon a cylinder like a roll of cloth. By this curious contrivance, it is said that more than one hundred sheets of veneer are produced in a single day, each sheet being nearly one hundred feet in length.
trivance veneers of any size may be produced, and the wood may be converted without waste into sheets so exceedingly thin that some have been used for covering or binding books. The appearance of the grain is of course somewhat different to that of veneers cut in the usual way, and it is said that the veneers cut by knife-edge machinery are not to be polished as those cut with a saw, since the surfaces being furrowed by the mode in which the fibres are, as it were, torn away from each other, instead of being intersected by the saw. So rapid is the action of the Russian spiral veneer-cutting machine, that it will produce 100 feet in length of veneering in three minutes.

The application of knife-edge machinery to the cutting of wood has recently excited much attention, owing to the establishment, by Captain Taylor, of a factory for barrels and similar articles by such means near Waterloo Bridge, London. Having reduced the work which is to be converted into staves to blocks of suitable length, the process is to steam them in ovens or boxes similar to those used by shipwrights for steaming timbers to be bent, and then to cut them into the required form by cutters worked by machinery, wares on the in a softened state. By various machines the several parts of a cask or other vessel are shaped with greater regularity than could be accomplished by hand, and with astonishing rapidity; and they are finally fitted together by similar means. The same kind of machinery is applicable to the cutting of park-paling and many other articles; and so great is the power of the cutters upon wood which has been properly prepared, that a person who witnessed experiments upon various kinds of wood, reported that the knife went through a log of African oak with as much ease as if it had been a piece of new cheese.

WOODCOCK. [SCOLOPACIDE, vol. xxii, p. 85. ]

The Lectures on the Laws of England were edited in 1834, in 3 small volumes, 8vo., by W. R. Williams, D.C.L., who observes in the preface that these lectures seem to be as superior to the Commentaries of Blackstone in accuracy and justice, as the latter is to the former; and, that they are inferior in elegance of style and charm of narrative; or, to speak in plain terms, the editor means to say that the Lectures are superior to the Commentaries in all matters which constitute the merit of a law book; and he is quite right, inasmuch as a student who would be familiar with the Commentaries, instead of reading Blackstone, would learn nothing of English law. The editor's notes are useful.

WOOD-ENGRAVING is the art of producing raised surfaces, by incision, on blocks of wood, from which impressions can be transferred by means of a coloured pigment to paper, or other suitable medium, and generally applied to pictorial representations of objects.

The art of cutting both upon metal and wood for other purposes than those which are now understood as printing, as well as that of shipwrights, has been greatly improved by the invention of the engraving press. [ENGRAVING.] The Egyptians indeed seem to have made a very close approximation to printing. Some of their wooden stamps are yet remaining, and are perfectly capable of giving impressions in the manner of our present wood-cuts, though their use was not intended for the stamping on clay or other malleable material; bricks so impressed being frequently found, of which some are in the British Museum. We give, in the next column, a specimen of one of these stamps, found in a tomb at Thebes, and brought to England by E. W. Lane, Esq. The originals were cut in hard wood, and were of the size of a quarter of an inch, the edges of wood: but the process of wood-engraving to the production of a book originated, there can be but little doubt, in China, and about the middle of the tenth century, although it has been established, chiefly on account of the silence of Marco Polo, whose work was written in the last two or three years of the thirteenth century. The omission is certainly remarkable; yet on the other hand the date here given does not ascend to the period of Chinese sable, but to a period which is reached by sober historical research in the dynasty under which it is thus stated to have been invented (that of Soong) became remarkable for the rapid development of literary genius that took place under it. It is stated that the first essay in printing was made by printing on stone, and then transferring the impression to paper, and the characters of their language being thus white and the paper black, as in the example given in the cut above. This rapidly relinquished for the use of wood blocks, in which the characters were cut in relief, and the appearance of the characters or pictorial representations, which occasionally form a whole volume, the subjects being sometimes connected so that each page is from a separate block, they would and produce a total length of some hundred feet. Sometimes the illustrations to the Wain Show, pieces of music and songs sung in the streets on imperial birthday being a series of representations of the public entertainments and exhibitions, horse-racing, foot-racing, etc., of which there is a copy in the library of the Asiatic Society. The work itself is 6 vols., of a size somewhat larger than that of an ordinary pamphlet, and the illustrations form a separate volume of several hundred pages.

The method used by the Chinese is to stereotype the wood, that is to say, to rub the picture to be printed with a paste or size, occasionally made of boiled rice, which renders it quite smooth, and at the same time softens and otherwise prepares it for the reception of the characters. The future pages, which have been printed by the method described in the present paper, are delivered to the block-cutter, who, while the above-mentioned application is still wet, unites them to the block so that they adhere, but in its inverted position, the thickness of the paper disposing the writing perfectly through the back. The paper being subsequently rolled off, a clear impression in ink of the inverted writing is taken, and by pouring the ink on the surface of the block an immaterial point. Strictly speaking the press of China' would be a monographer, as no press whatever is used in their printing. The paper, which is of a thin and absorbent, or absorbent of ink, as we call silver-paper, receives the impression with a gentle contact, and is
arder pressure would break through it. The printer holds in his right hand two brushes, at the opposite extremities of the same handle; with one he marks the face of the characters, and the paper being then laid on, he runs the other brush over it so as to make it take the impression. They do this with such expedition, that one man can take off a couple of thousand copies in a day.

In Europe the first application of the art of wood-engraving took place in Germany, though the process is not exactly ascertained, but is supposed to have been near Nürnberg, about the close of the 14th or beginning of the 15th century. It was probably first used for the production of playing-cards, the outlines of which were formed by impressions from wood-cuts, and the colouring filled up by hand; or we dismiss as utterly unfounded the story told by Paullin, in his Traité de la Gravure en Boss, of impressions of a series of wood-cuts seen by him, of a date between 1324 and 1329, executed by Alexander Albericus, in his town sister; although the story is believed by Ottley (Inquiry into the Early History of Engraving), and Zanci (Materiali per servire alla Storia de' Progressi dell' incisione in Rame e in Legno). Cards were known in France in 1340. John I. of Castile issued an edict against the use of them in 1380 (Buller, Recherches Historiques sur les Cartes à jouer). In the same year, in a book of the bye-laws of Nürnberg, they are included among the games allowed to the citizens, provided the stakes did not exceed ten pennies. (Von der Quellen zur Literatur und Kunstgeschichte, part ii.) In 1418 the burgess-book of Augsburg contains the name of a 'Kartenmacher' or card-maker. The trade in cards from Augsburg, Nürnberg, and Ulm became so great that Venice prohibited imports, and in Sicily they were imported by the cask. It is then that it must have been by means of some facility in multiplying copies that they could have been manufactured so cheap as to command so extensive a demand in foreign countries, but none of the specimens now existing enable us to fix any precise date to their production.

We give one specimen, copied from Mr. Singer's interesting work on playing-cards:

---

The first wood-cut with a date known to be in existence is of 1425. It was discovered by Heincken, pasted on the cover of a manuscript in the library of the convent of Boxheim, near Memmingen in Swabia, and is now in the library of Earl Spencer. It represents St. Christopher carrying our Saviour on his shoulders across a river. The two figures are drawn with much spirit; but the accessories, a man with a loaded ass, a hermit holding up a lantern, a man ascending a steep path, toward a house, show a depraved want of knowledge of perspective. It is by no means certain however that this print is the most ancient specimen we possess, as there are several others which from their greater rudeness, have been held to have superior claims to antiquity. This rudeness cannot be accepted as a proof, as there is reason to believe that these scriptural subjects were addressed to the wants of the poorer classes, and were intended to supply the place of the more costly illuminations of the rich, while they admitted of being made to occupy a middle place by being finished off by hand in colours, and indeed many of the remaining specimens owe part of their rudeness to the defect of parts intended to be so supplied. Cheapness was therefore an element necessarily required in the production of these prints.

The art however made rapid progress. The next great step was the production of black books and the adoption of movable letters. (Papworth.) Without entering into the disputed question of the date of the 'Biblia Pauperum,' the 'Speculum Salvationis,' and others, it will be enough to say that they prove the extension of its use, and many of the early books with moveable types were illustrated with pictorial wood-cuts. Of one of these works we subjoin a fac-simile specimen:—

---

Who Men's Offering.

Maps also were engraved on wood. In an edition of Ptolemy, printed in 1482 at Ulm, there are twenty-seven; and in a later edition, printed at Venice in 1511, the outlines, with the mountains and rivers, is in wood, while the names are printed with type, and in two colours, no doubt by separate workings. In England the original map of London by Aegagros, measuring 6 ft. 3 in. by 2 ft. 4 in., to which the date of 1560 was assigned by Vertue, though it was probably some years later, was on wood. In several blocks worked on separate sheets of paper. In 1486 the improvement known as 'cross-hatching,' by which the bold and free effect of a pen-drawing was endeavoured to be attained, was shown in Breideneck's 'Travels,' printed at Mentz. This invention has been usually attributed to Michael Wolgemuth, the master of Albert Dürer. This work however preceded by seven years the Nürnberg Chronicle, said to be by Wolgemuth, but who probably only furnished the designs, and the execution of the cuts is in a very superior style to that of any existing contemporary production; two fac-simile specimens are given in 'A Treatise on Wood-Engraving, Historical and Practical,' executed by J. Jackson.
the most complete work that has been produced on the subject in this country, and to which we are much indebted, although we have been compelled to differ from some of the opinions therein.

The art had now attained an excellence which induced artists of celebrity and talent to select it as the means ofdiffusing their designs to the public. Among the distinguished in this line was Albert Dürer, whose productions as a painter, and an engraver on copper and wood, are so numerous as to excite a doubt whether he was actually an engraver on wood himself, or whether he only put the designs on the blocks himself, leaving it to his father's hands to execute. Bartsch, in his Print-Graver, and the writer of the work above mentioned, A Treatise on Wood-Engraving, have agreed that he did not engrave on wood. The last named says, of all the wood-engravings marked with the initials of Dürer, about two hundred, "the greater part of them, though evidently designed by the hand of a master, are engraved in a manner which certainly denotes no very great excellence, and that none are so superior as to challenge a belief that they must be from his own hand; but he goes on to say that, of the cuts of the Apocalypse (published in 1498, five years after the Nürnberg Chronicle, and eight from the expiration of his apprenticeship) generally are much superior to all wood-engravings that had previously appeared, both in design and execution. Yet he adds that, for this superiority in execution does not arise from any delicacy or skill in the engraving, but from the ability of the person by whom they were drawn, and from his knowledge of the capabilities of his instrument. A frequent example is to be found in his cuts of cross-hatchings, a work of no artistic difficulty, though one of minute and tedious labour, and which, as an artist, he could have easily avoided. This argument is also applied to others, Cranach, Burgmair, &c., who, it is urged, could equally have made the cuts of the Apocalypse, if he had done them himself. But, as the art was most likely to have been acquired by practice, a fact that is felt even at present by persons who draw on wood; and it is remarkable that in the Apocalypse the use of cross-hatchings is much more sparing than in many of his later works, in the probability of the advanced in reputation he availed himself of assistance not only in wood-engraving, but in painting and engraving on copper. It is known that he had many pupils, and of course it is supposed that they cut the wood, marked precisely as his engravings on copper are marked, and we think there are thus grounds for supposing that the cuts of the Apocalypse are chiefly from his own hand, and that in the others he at least considerably superintended the execution, and arranged the finishing touches. The writer says there is a difference in the cases of the engravings on copper and wood; that the latter, if the design were transferred, could be executed by a workman of moderate skill, while the former would require a first-rate engraver. From this we dissent; there is much, no doubt, that patient fidelity could successfully copy, but there is much of artistic feeling and expression that none but an artist of great talent could reach: we refer as an example to the Christ taken from the Cross, of which both the drawing and composition I have seen in the possession of Mr. Blackwood, in the third edition of his History of Engraving, and in which the cross-hatching is but sparingly though effectively introduced. It is yet a common practice for engravers to employ their pupils in the most tiresome parts of their business, which might lead him to adopt the cross-hatching more frequently than in those executed by his own hand, in which however he would not altogether omit it, as it was used to give the impression of ink in an impression, which would be harder to eradicate; but in such cases to withhold the merit of the engraving from the master because he had been assisted perhaps by various persons, according to their capacity, under his immediate supervision. This is also Oltley's opinion. He says, "Dürer or Burgmair might have found employment for a dozen young men;" while the Abate Pietro Zani, in his more recent work (Encyclopaedia Metodica critico-ragionata delle Belle Arte, Parma, 1821), contends with great strength of argument for Dürer being actually the engraver of the wood-cuts attributed to him. Indeed the writer whom we are replying to admits he may have engraved them himself, or three or four hands, "but might have had engravers in his house to execute the designs under his own superintendence." But this seems to admit the whole case. Thus much we have thought it necessary to urge in favour of Dürer's claims to be considered as an engraver on wood, though doubts have arisen as to his being an artist to be estimated rather from his other works as a painter, an engraver on copper, and as a sculptor, in all which he excelled. In the history of the art too, the importance of the prints exists, the date of their production is well known, the progress of improvement definitely marked, yet the engravers have been who they might. But in an art that has thus rapidly advanced, and was coming into general use, if the designers and the engravers were distinct, it is not most probable that the excellence of the latter would at least have obtained in some cases a particular mention, as was done in a later stage, and is the practice now.

In the early part of the sixteenth century several of the greatest artists were either on wood or engravers, Louis Cranach, Hans Burgmair, Hans Schaffhausen, Uff Grafie of Berne, and, in Italy, Ugo da Carpi. Their initials or monograms are on the works, but their claims to be engravers have been denied by Bartsch and the writer of the Treatment on Wood-Engraving, as they were wholly insufficient ground of the execution not being good enough. To Da Carpi has been attributed the invention of imitating drawings in chiaro-seuro, effected by single blocks, two of which have been produced, but it has been done earlier by Cranach, though Da Carpi most certainly improved on it, and some of his designs are said to have been drawn on the blocks by Raffaelle himself, and many of them are from his designs. Books were also given as proof of this practice, produced about this time, and the cooperation of those from the artists already named, and very few others of some though inferior merit, the illustrations are very rude both in design and execution. The art was chiefly practised in Germany, being greatly patronised by the emperors of the Holy Roman Empire. The book of Bartsch, The Triumphs of Maximilian, was the only distinguished name out of that empire of the period, and the Italian wood-engravings are, on the whole, even inferior to those produced in the Low Countries.

The most prominent German engraver in all probability was Hans Holbein. He was born about 1498, and began early to distinguish himself as an artist. In 1528 he left Bassi, where he had hitherto resided, for England, having previoudly been instructed. His name is mentioned in the registers of St. Peter's, as he had executed a large full-length likeness of himself in wood, the block of which yet exists in the public library at Basle. The writer in the Treatise on Wood-Engraving says, there is not the slightest reason for believing that he was a pupil at either Dürer or Burgmair; and that he cannot get up his port of his theory, that Holbein never engraved on wood at all, but was merely a designer, as he had previously argued was the case with Dürer and others. This theory is developed chiefly in reference to the first edition of the Dune of Death, printed at Lyon in 1538. There had been several representations of a Dance of Death, some painted in fresco (one in the cloisters of St. Paul, London, and of the time of Henry VI.), and some in books, of which Mr. Deacon has given a list; but those of Holbein are far superior in spirit and expression that have ever been so excelled, though wanting in mere mechanical dexterity, as shown particularly in the foliage of trees and other subordinate details. Mr. Deacon, however denies to Holbein the invention of the designs, as the writer in the Treatise on Engraving denies his being the engraver. The doubt in both cases arises principally from a passage in the dedication to the Duke of Norfolk, and the expression in the preface to the Lyon edition, that it would be hard to demonstrate that Holbein made the cuts. The "death of him who has imagined such elegant figures as are herein contained," adding that Death, "apprehensive that the artist could thus become immortal, determined to shorten his days, and thus prevent his successor from having even a fragment of his work," the unfinished subject is then described, the Waggen, which however was supplied in a subsequent edition, but varying considerably from the descriptions, and not equal either in design or execution to the rest of the original.

WOO
series. Some words seem to apply to both engraver and designer—a finishing subject which he had already drawn. Holbein however did not die till 1564. Again, one of the blocks is marked with the monogram (H.L.) which Mr. Dance considers to be that of the designer, and the writer in the *Treatise* as that of the engraver. Holbein was an artist of high merit as a painter and engravers now, while the author of the ‘Dance of Death’ and other contemporary designs are not distinguished as an architect. Is it conceivable that he would at this period of his life execute the designs of another in an art subordinate to what he actually practised? The same year also, 1538, was from about this time that the publishers, ‘Before the Sonne, and after the Sunne’ were applied to wood-cuts at that time. The number of cuts is thirty-two, of which the first four are the same as in the *Dance of Death,* the remainder being of an oblong form, except one, which is printed in a different type and design, and is ascribed to Sandrart, among others, who was himself an engraver as well as a painter, in his *Teutsche Akademie der edlen Bau-Bild und Mahleren Kannte,* 1673-79, describes Holbein, as well as Dürer and others, as a wood-engraver. With regard to the cut marked ‘Figures of Death, with the names of the four elements’ as the mark of the engraver (whoever he may have been, for it is a contested point), and as little that it marks the cut he engraved as an exception to the rest. The statement of the first cut having been left unfinished may have had reference to the engraver for the block, the second cut having been engraved by Holbein in 1538, late in the year, but for too short a time to have executed them then and there, but they may have been prepared in 1538-3, when he resided at Basle for a short time, or in England, as were the cuts to Tindale’s New Testament bound at Antwerp in 1534; and the frontispiece to Coverdale’s Bible, printed at Zürich in 1535. The unfinished blocks may on either case have remained so from hurry or accident; but at least the statement goes to show that Holbein not only in the execution of the designs himself, but also to finish the subjects he had already drawn. It ought to be borne in mind that at this period artists throughout Europe confined themselves to no one branch; the same individual was painter, engraver, sculptor, and sometimes a printer in his own house, and there was no need to adduce examples. No doubt has been raised that Holbein engraved upon copper; why is it to be now doubted that he engraved upon wood? It is said; the head of Erasmus, the head of Sir Thomas Wyatt, the Bible cuts, all cut by himself, as printer and engraver. ‘Censure the man in his mind, not in his work for money?’ he produces the article for which he is paid. Without knowing every circumstance under which every cut was produced, we cannot decide by the mere rudeness of execution whether they are from his hand or not.

evory case however, there is a certain style, a finessed and freedom of line, an avoidance of all mechanical trick, and a simplicity which characterizes the productions usually attributed to him. We do not suppose indeed that he performed all the labour himself, but that it was done under his supervision, as similar things are done by eminent masters to-day. Mr. Dance in addition, that the capability of drawing well on wood, and adapting the style to cutting, is no slight proof that the artist himself can engrave; and few persons will excel as engravers who are not capable at least transferring a design to the block.

From this epoch the art has continued to flourish. The pupils of Bewick were numerous and possessed of great talent; the celebrity of their master procured them immediate employment. Illustrated works became fashionable, and the engraver, at first very little looked after, was by degrees, and particularly by the example of the *Penny Magazine,* wherein it was proved that a low price was not inconsistent with a high degree of excellence in the art of wood-engraving; and as it was thus brought within the reach of the very
poorest, the public were familiarised with the best specimens, and a large sale was ensured.

For the purpose of illustrating books wood-engraving is principally used. Being worked in the same manner that type impressions are produced with great rapidity. Any number of cuts may be printed at once on a sheet of paper that will come into the press or machine, and an almost infinite number of impressions may be taken off without material injury to the plate. This produces the copper plate art. The attempts which have been made to imitate the effects of copper-plates are misapplied, and the advantages have been failures. The extreme neatness, length and sweep of line, and bold outline of the copper cannot be re-created in wood-engravings, while in depth of shadow and effect they equal even mezzotint, with more distinctness of detail.

It is not necessary to detail the history of wood-engraving beyond this period, as many of Bewick's immediate successors are yet living, through the mistake that it is difficult to conceive that a higher degree of perfection can ever be attained than that now realised by our present artists, while the designs are frequently furnished by artists of the highest eminence. Within the last few years also the wood-engravers of France, and also of Germany, have made such progress in improvement as to become no contemptible rivals of their English brethren. Nor is it any part of our plan to give practical instructions for engraving, which can be more effectively performed by instruction in practice. A description of the process as practised in his time is given by Papillon, in his 'Traité de la Gravure en Bois,' 1766; and a far more detailed account, with all the modern improvements, by Mr. Jackson, in the 'Treatise on Wood Engraving,' already mentioned. It may serve that one of the greatest practical improvements, that of lowering the surface of the blocks in parts, so as to gradually shadow the lights, was, though not invented, yet brought into use by Bewick, nearly all his blocks being so prepared for engraving; and that his wood is now universally used for engraving upon.

(Ottley's Inquiry into the History of Engraving on Copper and Wood; Singer's Researches into the History of Playing-Cards; Treatise on the History of Wood-Engraving, with upwards of one hundred Illustrations, engraved on Wood by John Jackson; Heineken, L'Idée Générale d'une Collection complète des Cartes.)

WOODYALL, William, was the son of the printer and proprietor of the 'Public Advertiser' newspaper; another son, we believe the elder of the two, was Henry Sampson Woodyall, who succeeded his father in the management of the paper, and held it when it became the means by which the letters which the letters of Junius were given to the world. William was born in 1745 or 1746, and began life by being sent to learn the printing business under Mr. Baldwin, of Paternoster Row. He was then employed for some time in assisting his father in printing and editing the 'Public Advertiser,' and that time for the first time his abilities were noticed, though not possessed of him, that he broke away with a company of players on an excursion to Scotland to gratify that passion. While in Scotland he married, but returned to London about 1772, when he was first employed for a short time as editor of a newspaper called 'The London Packet,' and then undertook the direction, both as editor and printer, of 'The Morning Chronicle.' With that paper he remained connected till 1779, when he left it and set up one of his own, which he called 'The Diary.' Before the close of 1780, he had published an 8vo. packet of 'Psalms,' (prior 36. ed.) a Sketch of the Debate in the House of Commons in Ireland upon the rejection of the twenty commercial propositions; but it was in 'The Diary' that he first gave public notice of an attack on the subject of the separation of the press, and pursued his readers with as detailed accounts of the parliamentary debates on the day after each took place, as the other papers had been in the habit of supplying after an interval of many days; for the practice then was to give them in summary in an alphabetical manner, and to add the full speeches till the reports of them could be prepared at leisure. Woodyall's mode of proceeding was what would now be thought very extraordinary. 'Without taking a note to assist his memory,' says the notice of him in the obituary of the newspaper in which he was employed, 'he would sit at his table and tell his readers, without the use of a memorandum to ease his labour, he has been known to write sixteen columns, after having sat in a crowded gallery for as many hours, without an interval of rest.' This exercise however, it is added, in which he took pride, and which brought him more praise than profit, 'was done with a firmness, which was marvellous good; and when done, by the division of labour, produced the most perfect reports of debate, with an earlier publication, he yielded the contest, and suffered his 'Diary' to expire.' In his later years he offered himself a candidate for the office of Otterton. Before embracing it, however, he married Mrs. Wood, became an actor, and also wrote several novels.

(Annual Register, vol. 45.)

WOODFORD. [Eccle.

WOODBUSH, Robert. There is almost a real silence concerning this printer, who was formerly attached to the office of The London, but who after that he became editor of the Gentleman's Magazine. He died in 1758, and was succeeded by Dr. Scott, the editor of the Gentleman's Magazine.

Robert Woodhouse was born at Norwich, April 3 1773. His father was in business in that city, where he was one of the principal printers, and possessed a considerable library of some antiquity, and claimed and sought to recover a seat at Eton, in the possession of Lord Byron, as the uncle of the poet. His mother was the daughter of Rev. J. Alderson of L.-westoffe, who was the great-grandfather of Bishop Heywood. He was educated at Eton, and afterwards at Cambridge, and in 1795. He gained a fellowship at an college (i.e. the fellows, or most of them, may continue laymen), as the concerns of the College and University, with his wishes to private pupils, and turned his attention to be a professor of mathematics; and in 1822 was removed to the Plimian professorship of astronomy and experimental philosophy, vacant by the death of Dr. Vince. In 1823 he was married Harriet, the sister of William University, R.A., the president of the Royal Academy, and to whom he dedicated his 'Life of Lalande.' In 1824, when the Observatory was completed at Cambridge, he was appointed to be its superintendent; but by this time his health had failed, and he was hardly equal to the extent of his duties. He left Lalande in 1827, and was buried in the chapel at Caius College.

Woodhouse is distinguished as the first who, in his University, cultivated the methods of analysis which the genius of the Continental mathematicians had made so much of. The last was exclusively taught in England at the time when he graduated. He was the first who introduced the method of analysis into a work (or at least published) for the English student, and he must therefore be considered as the leader of the movement by which the mathematicians of this country assimilated their methods to those of their Continental brethren. For this position he had perfect qualifications: a profound and extensive knowledge of every stage of the progress of all that he studied. The last work he published, at the age of 82, was a treatise on the elements of analysis. To these we must add a high personal character, and the esteem of his contemporaries;—the consequence of the utmost consequence to a literary reformer. His style of writing is peculiarly his own, frequently difficult to understand, and frequently wanting in the modern mathematician, a perfect absence of discipline; ability to see that much of his importation was as inferior in accuracy as it was superfluous, and, in an age so much given to expediency, to introduce a new and different form of amendment. To these we must add a high personal character, and the esteem of his contemporaries—qualities which make out a meaning, Woodhouse is a favourite name;
still more so with those who like to think about the first principles of their subject. But to those others who pour intellectual fervour and understanding there is a sort of metaphysical symbolism which they have made out as an author as soon as they see how his sentence runs, he is regular; and still more so to those who are rather bent upon using mathematical symbols than understanding them.

We do not mention his papers in the 'Philosophical Transactions,' as their principal points are repeated in his separate writings, which are as follows:

1. 'The Principles of Analytical Calculation,' Cambridge, 8vo., 1803. In this work, which is rather of the descriptive and controversial than of the elementary character, the method which is well known as that of the language and first principles of the Continental analysis, with strong recommendation of the former, and a searching criticism on the latter. He passes under review the method of infinitesimals, limits, expansions, &c., and the total insufficiency of the method of Lagrange [Poncelet, Tirony op], and gives his own views of the mode of establishing the differential calculus. He had evidently, as often happens to those who strictly investigate received facts, been an original thinker, and had a talent for and an ability in the use of the possibility of any rigour at the outset, at least an instinctive habit of objection. Though differing from several of his positive conclusions, particularly those which he comes to on the character of the theory of limits, we must always see in him an independent thinker indeed in which he is so individual as to distinguish the work throughout. Considering the time and place at which it was published, it is a rare instance of enterprise in the choice of a subject and of the manner of treating it.

Of the other qualifications of a controversialist, Woodhouse had a power of sarcasm, which, though in private life it only went the length of what is called 'dry humour,' yet appeared now and then in his writings in a manner which would have made an opponent careful what he said, and a friend blush at the expenses he incurred in the production of greater merit, and such as is not likely, notwithstanding the crowd of similar publications in the present day, to be specially superseded in the business of education; and, as some subjects are, well calculated to fix strongly the attention of the student, and to make him reflect attentively upon the particular processes which are followed, and upon the reasons for their adoption. The 'Analytical Calculations' was an exception in this respect, and was addressed to the student. It excited the opposition of those who were attached to the old system, and paved the way for the subsequent introduction of the differential calculus, the works on which must have been accompanied by treatises to show them to themselves, if Woodhouse had not supplied the want.

S. 'Elements of Trigonometry,' Cambridge, 8vo., 1809 (several subsequent editions). Of this work Dr. Peacock says that 'more than any other contributed to revolutionize the mathematical studies of this country. It was a Nemesis to the science, and led to a period of original study, which produced a new way of looking at it, and of discussing it. It had the effect in the study of mathematics, of great merit, and such as is not likely, notwithstanding the crowd of similar publications in the present day, to be specially superseded in the business of education; and, as some subjects are, well calculated to fix strongly the attention of the student, and to make him reflect attentively upon the particular processes which are followed, and upon the reasons for their adoption. The 'Analytical Calculations' was an exception in this respect, and was addressed to the student. It excited the opposition of those who were attached to the old system, and paved the way for the subsequent introduction of the differential calculus, the works on which must have been accompanied by treatises to show them to themselves, if Woodhouse had not supplied the want.

3. 'A Treatise on Isoperimetrical Problems, and the Calculus of Variations,' Cambridge, 8vo., 1810. There is something peculiar to himself in every work which Woodhouse produced. The mode of writing scientific history, which Delambre afterwards adopted, is here for the first time: it consists in taking up the subject in such a manner that its history in the hands of each individual is separate from the rest; accordingly, the method of tabulating the names of the author, the year of its preparation, its promoter, and its connexion with it. Woodhouse puts distinctly before the reader the very problems, methods, and notation of the several writers on the calculus of variations, from the first original writers down to the most recent. To this end he has supplied a table of the names of the authors, the title of their works, and the date at which they were published. The book will not pass away like an elementary work; it is a history.

4. 'A Treatise on Astronomy,' Cambridge, 8vo., 1812. The first two volumes of this work, which was published in 1818, is on the theory of gravitation, which is somewhat improperly called Physical Astronomy. But in the subsequent editions the first volume was enlarged into two, which were obliged to be called parts; so that we must now consider each as being divided into two. The first part, in which the scientific element introduced as an hypothesis, and the second, in which physical astronomy, or the theory of gravitation. Of the latter it is only necessary to say, that it was the first work in which the student was introduced to what had been done abroad since the death of Newton, and that it does not retain its place only because the subject has advanced both abroad and at home. But the first volume still remains perhaps the most remarkable work on astronomy of its century. This distinction it owes to the manner in which Woodhouse makes the reader feel that he is in the very observatory itself. The methods are as perfect as if they had been directions to a computer, a quality which writers who have to explain those methods mathematically frequently do not give them; the examples seem as if they were real ones, as if some astronomer had had to put down the actual figures, and the very observations may be thought of as if they had been taken while the astronomers which gave them. Many theoretical works on astronomy may make a reader think he would like the practical part of the science, in which he may afterwards find himself mistaken; but Woodhouse's treatise cannot deceive him in this respect; he will or not rely partly from according as he is or is not pleased with Woodhouse's book. At least the preceding is more true in the spirit book than of any other. The secret was, that the sense of his subjects, his reputation as an original thinker, and his first place with the student in an unusual degree. He was very fond of the subject of practical astronomy, a taste which is not always found in the mathematician, and so he was able to form a system of the whole of the work, a system which before the failure of his health, he would probably have become as distinguished in the promotion of astronomy as he was in its explanation: as it was, he had only time to discover [Transit, p. 124] the enormous effect of the diagonal branches of the transit instrument.

The character which must be given of the several writings of Woodhouse entitles us to suppose that the revolution in our mathematical studies, of which he was the first and most active agent, would not have been brought about so soon if its earliest advocacy had fallen into less judicious hands. For instance, had he not, when he first called attention to the continental analyses, exposed the unsoundness of some of the usual methods of establishing it more like an opponent than a partisan, the change which would have probably have made a successful stand against the whole upon the ground which, as it was, Woodhouse had already made his own. From the nature of his subject, his reputation as an original thinker, and his first seat in the world at large: but the few who can appreciate what he did will always regard him as one of the most philosophical thinkers and useful guides of his time.

WOODHOUSE, LORD. [TYLER, A. F.]

WOOD-LARK, Alauda arboea. Although this resident is not plentiful in Great Britain, it is scattered generally over the British Isles. Its length is about six inches, and its plumage a good deal resembles that of the Skylark, the head of a reddish-brown, and the breast of a greyish-white. Montagu well describes its habits. 'It sings,' says he, 'delightfully on wing; describing its flight in widely extended clycles, and pouring out its song a whole hour without intermission; it rarely utters its song when sitting on the ground, though sometimes when perched on a tree. The song is much more melodious than that of the Skylark, but does not consist of so great a variety of notes; but then it sings almost throughout the year, except in the months of June and July. It does not mount in the air in a perpendicular, but always soars to a great height, and keeps flying in large irregular circles, singing the whole time with little intermission; no other song has such an effect. The nest, which is early formed, for the Wood-Larks begin to build in March, is made of dry grass with a finer lining of the same, and a few hairs, on the ground, generally in uncultivated rough land, and mostly sheltered by bushes or thickets, or sometimes on a rock or cliff. The four or five eggs are brown, with dusky and mottled, most numerous at the large end. The Wood-Lark is rare in the North of England and Scotland, and has not been noticed in Shetland or the Orkneys. It visits Ireland in the summer, but is permanent in Germany, Holland, France, Spain, and Italy. The species is common in Sardinia, according to Mr. Strickland.'
It is the Lulu of the French; Tuttullina and Tuttavella of the Italians; and Baumlerche, Waldlerche, and Haidelerche of the Germans.

**WOODPECKERS, Picidae, a family of Scansorial birds.** (Scansores.)

The order Pici of Linneus is thus characterized:—

*Bill (cuneus sarrii) cultivated, with a convex back. Feet walking, short, rather strong. Body 'tenuisculum,' impure. Food 'quiulicium.' Nest in trees; the male feeding the incubating female; Monogamy. Order analogous to the Primates.*

This order seems to be the most arbitrary in the ornithological system of Linneus; for under it birds of very discordant habits are collected. The Woodpeckers, the Cuckoos, the Kingfishers, the Humming-Birds, are together associated with others in the following succession:—

**Picidae**.

Bill subcompressed, convex.

Genera:—Picus with its three sections; Ramphastos; Buceror; Buphaga; Crotophaga; Corvus; Coracias; Oriolus; Gracula; Paradisa; Trogon; Bucco; Caculus; Yunz; Picus; Sitta; Todus; Alcedo; Merops; Upupa; Certhia; and Trochilus.

The previous arranged the Wryneck, the Woodpeckers, and the Jacamar in the first section (Bill straight) of his thirteenth order of Birds—those, namely, with four toes, two before and two behind.

Latham's *Picidae* consist of even a more heterogeneous group, which he arranged under the general name of Picus of Linnaeus.

The fourth order of Birds, in the Method of Lcæpède, consists of those which have the bill straight and compressed, and under it two genera only, Galbula (Jacamar) and Caculus. The Count's third and fifth orders are formed respectively of the genera Bucco and Yunz.

The first family (Camerostes or Sphenorhamphes) of M. Dunéni's third order (Grimpeurs or Climbers) comprises the genera Picus, Yunz, Galbula, Crotophaga, and Caculus.

*The Pic i form M. Meyer's third order, and are divided into two sections:—*

1. With stiff feathers. Genera:—Picus; Certhia.
2. With soft feathers. Genera:—Yunz; Sitta; Tichodorus.

Illiger's *Scansores* consist of the *Picatini;* the *Serrati;* the *Amphiboli;* the *Sagittilungues;* and the *Syngactylsi.* The *Sagittilungues* embrace the genera Yunz and Picus.

The great genus Picus is placed by Cuvier in his third order, *Grimpueurs,* unlike Galbula and Yunz.

The *Syngactylsi* are the first tribe of the *Syngactylsi,* the second order of Birds according to the method of M. Vieillot; the second family of that order, the *Macrogrumii* of the genera Picus and Yunz.

The *Syngactylsi* are the fifth order in M. Temminck's arrangement; and the genera Picus, Galbula, and Yunz constitute the second family of that order.

The Cuckoos and the Woodpeckers form the *Syngactylsi* of M. de Blainville.

Mr. Vigors, as we have seen, separates the Parrots and Woodpeckers from the other families of *Scansores,* associating them together in consequence of their affinity in the essential characteristics of the tribe, and, in his view, they compose its normal groups, as clergiers par excellence, differing however as to the mode in which they climb: the Parrots using the foot chiefly in grasping the object which assists them in their ascent, and in conjunction with the bill; whereas the *Picatini* rely upon the strength and straightness of the hind toes in supporting them in a perpendicular position on the sides of trees, in which posture they are also assisted by the strong shafts of the tailfeathers. Not that some of the *Picatini* do not partially assist in supporting themselves as they climb, in a corresponding manner with the Woodpeckers, for Mr. Vigors makes the remark that they do, particularly *Picatus and their congeners,* from his own observation. The tongue too, he states, peculiar to the *Parrots,* may be observed to become slenderer, and, as has been said, more extensible, in that group of which *Picaus aterrimus,* Gm. is the representative; thus evincing, Mr. Vigors adds, an approximation, slight indeed, but still an approximation, to the bill of the Woodpeckers.

Mr. Vigors recognised in the Linnean Barbers a group apparently intervening between the *Picatini* and *Picidem,* and diminishing the distance that exists even in the form of the bill. That important group, to his evidently exhibited the expected gradation in the structure of that member; the bill of *Pogonias* approaching nearly that of the *Parrots,* by its short, strong, and beak-like conformation, to say nothing of the frugivorous habits of the *Barbet,* while the straighter and more lengthened bill of the true *Bucco* united itself to that of *Picus,* in other particulars in form, and also an extraordinary formality in colouring, still further pointed out the close and he was at length confirmed in his conjectures regarding the situation of these birds, by arriving at the knowledge of their habits being actually those of the Woodpeckers, and of their chief affinity being the group. Thus Mr. Burchell, in his interesting "Travels in Africa," mentions a little noisy *Barbet* (*Pogonia Bucico nigri,* Gm.), which the Hottentots call *Kepper* (Woodcutter) from the noise it makes in the tree.

The attention of Mr. Vigors was first called to the peculiarity in the manner of the *Barbet* by Mr. Swainson, to whose friendship, he states, he is indebted for much valuable information in his inquiries into the affinities of birds on his travels. Mr. Legros, during his regular graduation by which *Picatini* and *Picidem,* united in their general characters—and those the characters most prominent and typical of their own tribe—and also united in their minute peculiarities, is indebted to Mr. Vigors for these still more corroborative proofs of the interrelations these birds between the *Parrots* and *Woodpeckers.*

Mr. Burchell also entered into a detailed account of the affinities, before a meeting of the Zoological Club of London, of September 1809, and the 1st of October, from his observations during his travels. The regular graduation by which the *Picatini* and *Picidem,* united in their general characters—and those the characters most prominent and typical of their own tribe—and also united in their minute peculiarities, is indebted to Mr. Vigors for these still more corroborative proofs of the interrelations these birds between the *Parrots* and *Woodpeckers.*

"We are thus," observes Mr. Vigors in continuation, introduced to the family of *Picidae,* a very important and well-defined group, both in manners and general appearance. If it is composed of a group of *Pogonias,* III.; in some species of which the sexes are gradually lost, or rather changes into the entire bill of some of the shorter-billed species of the true *Bucco,* that succumbed. The bills of these again lengthened, and nearly assimilated to that of the *Picus,* which comprises the greater portion of the family. A group of these, represented by the *Podastrum,* Linn., in which the shafts of the tail-feathers are soft and flexible, unlike those of the genuine *Picatini,* seems to reach round again as the *Parrots* generally commence. To these also the well-known genus *Linn.,* appears to be related. Mr. Vigors then refers to the strong affinity between the *Picatini* and the succeeding group of *Certhiadea* (Cranes),

*Affinis.*

Mr. Vigors then proceeds to the Orders and Families of *Sau- a.

The *Progothides* of M. Latreille are arranged between the *Cuculides,* and the *Grandiostrides* (Toucan Aracari); the *Progothides* consists of the genera *Pico, Picidas, and Picus.*

In the Method proposed by M. de Blainville in 1812 and 1821, and developed by M. Lhernard in 1827, the *Woodpeckers* (Picus) stand between the *Toucan and the Hoopoe,* in the first subclass of the *Aves.*

In the Project of M. Lecommon, the *Picidas* comprise the genera *Yunz,* *Picidas,* and *Picus,* and are placed between the *Cuculides,* and the *Ramphastides,* forming the fourth family of the first tribe (Syngactylsi of Java);

Mr. Swainson is of opinion that the structure of the *Picidas* constitutes them the most perfect of all the climbing birds, for nature has rendered them wholly subservient to this particular power. The toes, services, although very short, are unusually strong; the nails are broad and crooked, and the toes placed in such a manner that, is, two forward and two backward.
As an additional and powerful support in their rapid and perpendicular ascent up the trunks of trees, their tail-feathers, he remarks, terminate in points, and are uncommonly hard, so that being pressed against the bark, they aid the bird in its progress or in keeping its position. The bill is pointed for the labious operation of penetrating the wood or stripping off the bark of forest-trees, is beautifully adapted for the purpose, being wedge-shaped, furnished with regular-sided angles, and in one species (Picus principalis), nearly of the colour and consistency of the ivory-billed Woodpecker. Mr. Swainson then calls attention to the worm-like tongue barred at the point, and capable of being protruded to a great length.

---

Mr. Yearrell observes, that another anatomical peculiarity remarkable in the skeleton of the woodpecker, but admirably adapted to the habits of the bird, is the small size of the keel of the breast-bone. Moderate powers of flight, says this observing zoologist, sufficient to transport the bird from tree to tree, are all that it seems to require; large pectoral muscles with a deep keel to the breast-bone would to this bird be an inconvenience. The advantage of a narrow shallow keel is immediately apparent, on looking at a representation of the skeleton in a climbing position; the low keel, allowing the bird to place its body close to the tree, brings its centre of gravity in a perpendicular line before the points of support, and thus materially diminishes the labour of, and the strain upon, the muscles of the legs and thighs. The descending position of the bones of the tail indicate the mode by which the stiff points of the tail-feathers are brought into contact with the surface of the bark of the tree to form an accessory prop. (British Birds.)

---

Mr. Yearrell observes, that another anatomical peculiarity remarkable in the skeleton of the woodpecker, but admirably adapted to the habits of the bird, is the small size of the keel of the breast-bone. Moderate powers of flight, says this observing zoologist, sufficient to transport the bird from tree to tree, are all that it seems to require; large pectoral muscles with a deep keel to the breast-bone would to this bird be an inconvenience. The advantage of a narrow shallow keel is immediately apparent, on looking at a representation of the skeleton in a climbing position; the low keel, allowing the bird to place its body close to the tree, brings its centre of gravity in a perpendicular line before the points of support, and thus materially diminishes the labour of, and the strain upon, the muscles of the legs and thighs. The descending position of the bones of the tail indicate the mode by which the stiff points of the tail-feathers are brought into contact with the surface of the bark of the tree to form an accessory prop. (British Birds.)

---

In the opinion of Mr. Swainson the divisions of this family are strongly marked, because, as some few intervening forms are wanting, the circle is, in one sense, incomplete. Thus the Nuthatchers (Sittae), he observes, although clearly approximating to the Woodpeckers, are not directly united to them; neither does the intervention of the Wryneck, with its worm-like tongue, or even a small aborn, with its acute bill, do more than indicate the broken links of the chain. The absolute connection between the true Woodpeckers (Picinae) and the subfamily of Barbits (Buccininae) he thinks, unquestionably established by two very singular little birds, one being the Sturno Woodpecker of Lathamus (Chelumna, Scz.), the other a Barbit (Picinnus, Temm.).

---

The true Woodpeckers (Picinae, Sw.) are, Mr. Swainson observes, typically represented by the great ivory-billed species already noticed. The upper and lower edge of the bill in this bird exactly correspond. He remarks their inclination towards the tip, rendering the organ perfectly straight wedge. The construction of the bone out, rendered still more perfect by a ridged, narrowly crenated hard, and is situated nearly half way between thick and
ternal margin of the upper mandible. Mr. Swainson then draws attention to the crests in these birds—short, rigid, and turned upwards; but their chief generic distinction rests, in his opinion, on the structure of the feet, the hinder external toe being manifestly longer than that in front: this peculiarity, he observes, even extended to such aberrant species as have one of the small toes wanting. In the two northern species, Atsphenus iridifrons and A. arcticus, for instance. To this group therefore he restricts the generic name of Picus, which includes in his arrangement all the British species excepting viridis.

In the next group, Christophorus finds a diminution of the typical excellences; the bill, as in the Common Green Woodpecker, is still nearly straight, but the lateral ridge is close to the culmen, and the hind-toe is either of equal length or slightly shorter than the fore-toe: the crest, though more rigid, is less massive and not so much developed. Mr. Swainson remarks that the colours of these birds are always gray; green and soot-black predominate, and most of the typical species have the quills of a beautiful golden hue, whence the generic name above stated.

Dolichonyx is distinguished from Malacophus by the greater curvature and compression of the bill, and by the disappearance of the ridge on the upper mandible; thus, in Mr. Swainson's opinion, assimilating the group to the Tenenures, and exhibiting the weakest structure amongst the Woodpeckers.

Melanerpes, Sw., the fifth and last genus, may, Mr. Swainson thinks, be not unaptly called Swallow Woodpeckers, for they resemble those birds in their migratory habits, the broadness of their wings, and their black glossy plumage, destitute in the typical examples of spots or bands. Yet, continues Mr. Swainson, 'here we find nature has begun to return once more to her original type: the ridge on the bill is again apparent, at first but slightly, but finally very distinct; this menu, however, though not stride, is less arched than in Colaptes; the two greater toes are of equal length; the wings long and pointed; and the third quill equal or longer than the fourth; the black and white plumage, seen only in the typical genus Picus, is again assumed, the two lateral toes of the upper mandible is as in the last genus; but the anterior toe is longer than the hind-toe; the crest is long, formed of loose feathers, and, like the rest of the plumage, particularly soft; hence the generic name.

Galeus is distinguished from Malacophus by the greater curvature and compression of the bill, and, by the disappearance of the ridge on the upper mandible; thus, in Mr. Swainson's opinion, assimilating the group to the Tenenures, and exhibiting the weakest structure amongst the Woodpeckers.

Melanerpes, Sw., the fifth and last genus, may, Mr. Swainson thinks, be not unaptly called Swallow Woodpeckers, for they resemble those birds in their migratory habits, the broadness of their wings, and their black glossy plumage, destitute in the typical examples of spots or bands. Yet, continues Mr. Swainson, 'here we find nature has begun to return once more to her original type: the ridge on the bill is again apparent, at first but slightly, but finally very distinct; this menu, however, though not stride, is less arched than in Colaptes; the two greater toes are of equal length; the wings long and pointed; and the third quill equal or longer than the fourth; the black and white plumage, seen only in the typical genus Picus, is again assumed, the two lateral toes of the upper mandible is as in the last genus; but the anterior toe is longer than the hind-toe; the crest is long, formed of loose feathers, and, like the rest of the plumage, particularly soft; hence the generic name.

Colaptes is distinguished from Malacophus by the greater curvature and compression of the bill, and, by the disappearance of the ridge on the upper mandible; thus, in Mr. Swainson's opinion, assimilating the group to the Tenenures, and exhibiting the weakest structure amongst the Woodpeckers.

the margin of the upper mandible distinctly toothed. (Africa only.)

Yunx. [Wayneck.]

Oxyrhynchus.

Generic Character.—Bill as in Yunx, but the culmen more and the gwyns less curved. Wings lengthened, pointed; the first quill nearly as long as the second, with the outer web crested. Feet short, inessential: lateral toes equal. Tail moderate, even. (South America.)

The Picidae, in Mr. Swainson's arrangement, are placed between the Piculidae and the Certhiidae.

In the Geographical and Comparative List of the Birds of Europe and North America, by the Prince of Canino and Musignano, the Picidae, which are arranged between the Piculidae and the Certhiidae, consist of the following subfamilies and genera:

a. Picinae.

Genus Yunx. Mr. Gray places the Picidea (Picus, Linn., and Bucco, Linn.), his third family of Scansores, between the Piculidae and the Certhiidae. Mr. Gray's Picidea include the following subfamilies and genera:—

1. Buccoine.

2. Picine.

Genus Picinus, Temm.; Micropterus, G. R. Gray; sieia, Hodg.; Siria, Hodg.

3. Picidera.

Genus Picisdes, Lape.; Hemiscirus, Sw.; Campebuthus, G. R. Gray; Dendraboras, Piss., Picus, Linn.

4. Dryocoleine.

Genus Dryocopus, G. R. Gray; Dryocopus, Sw.; Xylocopinae, G. R. Gray; Xylocopinae, Sw.; Melanopera, Sw.; Tripsurus, Sw.

5. Celenina.

Genus Cecinus, Boie; Hemilophus, Sw.; Celenus, Boie; Metopistes, Sw.; Tiga, Kaup; Brachypterus, tricki.; Centaurus, Sw.; Leucopera, Sw.

6. Colapinina.

Genus Colaptes, Sw.; Gecolopus, Bureh.

7. Yunicina.

Genus Yunx, Linn.

Eurasian Woodpeckers.

Examples.—Picus martius, Linn. (genus Dryocopus, sieia; Dryocopus, sieia; Dryoscoenus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryocopus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococcus, sieia; Dryococ
tend to propel it forwards. This provision, the more needed from the posterior situation of the legs, is admirably calculated for ascending; and having explored the bank by a spiral course, the woodpecker flies off to the next tree to repeat the same process. The flight of the present species is undulating, seldom protracted to any extent, but limited to a transit from tree to tree in the seclusion of its native woods. Its food consists of the larvae of wags, bees, and other insects; in addition however it devours fruits, berries, and nuts with avidity. The female selects the hollows of old trees, in which she deposits two or three eggs of an ivory whiteness.

Mr. Hewitson saw this species in two instances only in Norway, and at a distance. The birds were so wild that to approach them was impossible. The same observing ornithologist says that on the wing the Black Woodpecker looks like a crow, and that its notes resemble a loud hoarse laugh.

The Great Black Woodpecker (Dryocopus martius).

*Description*—Male.-Top of the head, occiput, and moustaches brilliant red; face black, upper yarls a beautiful green; rump tinged with yellowish; quills regularly marked with whitish on their external bars; tail shaded with brown and striped transversely; base of the lower mandible yellowish; iris white, feet greenish-brown. Total length about thirteen inches.

*Female* with less red on the head and less black round the eyes; the moustaches black.

The Young of their departure from the nest have a little red upon the head, the rest yellowish ash-colour; all the green paler, and marked on the back with ash spots; the moustaches formed by some black and whitish spots; the rest of the lower parts greenish white with tawny brown bands; iris blackish ash.

*Varieties.*—Pure white with the head yellowish; its plumage of a dusky tawny, with the tail much tumbled; often more or less variegated with white.

This is the Pic verd and Pic vert of the French; Picus verus, Picchio verde, and Picchio polosco of the Italian; Grünspecht, and Fichter, Sand, Griener und Grünholz of the German; Gröngökling of the Swedes; Grosneet of the Danes; Norwegian; Deteau and Deteta of Scopoli; Green Woodpecker or Woodpige, Rain-bird, Rain-fish, Nibbe, Hubber, Howkole, Birt Bird, Pick-loh, To:ppinage, Vlug, Til, Yoffter, Woodcule & Whet-le, Poppiney, and other names given by the modern British; Gumell y coed and Dein y dera the antient British.

Below seems to confound the Great Black Woodpecker and the Green Woodpecker; his description and tags indicate the latter, but over the cut in *L'Histoire de Nature des Osyaxes* (folio, 1555), he writes Dryocopus, Pipra, Pipo, Chlorous en gree, Picus martius major, Picus roseus et arborum cavator en latin, Picus nit, ou Pic taulie en Franygo, and below he gives description of the Dryocopus (Dryocletes) from the ninth chapter of the ninth book of Aristotle *Hist. Anim* where the Greek zoologist states that Dryocopus does not perch on the ground, but strikes the oak or the walnut to break and insects (insects, he means the Green Woodpecker frequently hatches on the ground) to the purpose of feeding on them. In the *Pomme Osyaxes* &c. (4to, 1537), over the same figure, Dryocopus, L'Ornithologue des Laitiis, Picus maritus. Picus scolarius, Picus verus, Picus luteus, Picus niger, Picus martius, Picus taulis, Picus iner, Picus martius ou Picart, Pic verd, Pic taulis, Picmart; and below—

*Le Pic verd (mais) a la Turrette et done, au lieu de Corbeau et au rouge Pic verd.*

*Les autres, le Plumage est de brun, et ses petits on un trou d'afeur en beure.*

Further observations relating to the Woodpecker to the antients will be found at the end of this section.

**Geographical Distribution.**—The European Woodpecker is but not common in Holland, from Scandinavia and Russia to Spain, Provence, and Italy; the woodpecker of Greece, England and Scotland generally, where the species is rare. Not recorded as having been found in Ireland.

**Habits.**-Food, &c.—This species obtains its nourishment on trees and on the ground; its flight is short, quick, and rather laborious. When seen moving about, Mr. Yarrell says, its motion is directed forward or less obliquely, and is believed to be capable of descending unless this action is performed forwards. On flying to a tree to make a new nest the bird settles down on the bough or body of the tree a few feet above the ground, and generally chooses the lowest large branch, as if to have all its work at hand, proceeds from thence upwards, alternately tapping to induce any hidden insect to change its place, pecking in a decayed branch, that it may be able to reach sects that are lodged within, or procuring its long flexible tongue to take up any insect on the surface; but summit of the tree once obtained, the bird does not scend over the examined part, but flies off to another or to another part of the same tree, to recommence search lower down nearer the ground.

A very large proportion of the food of this species is derived from ants and their eggs. Every person who has lived in the country must frequently have seen the coloured woodpecker on its nest at some time or other. Mr. Yarrell states that he has seldom had an opportunity of examining a recently killed specimen, the beak of which did not indicate by the earth adhering to the base, and the feathers about the nostrils, that the bird had much forage at work. Bechstein says that in the latter part of the season the bees from the hive, and that unless it is fed on ants' eggs, and meat. Of its manners in captivity the German ornithologist says that the beauty of its plumage is all that can be said of it; for it is so foamy, quarrelsome and stubborn, that it can only be kept chained. In captivity he adds, to see it crack nuts, and eat the meal provided, is associated with enjoyment; and so differently has the nut been eaten that the Nutcracker has been placed near this bird.

Buffon laments over the hard lot of this bird, always condemned to labour for its existence, and bears in it all those laughing cry exclamations of wretchedness, which so much can hardly be unhappy while obeying an instinct which is associated with enjoyment; and so differently has the nut been eaten that the Nutcracker has been placed near this bird.
The nest is generally formed in an elm or ash tree, and when the birds are excavating the hole on which they have pitched for its place, they are said to carry their chips to a distance, for fear their presence on the spot should lead to discovery. The eggs, which are smooth, shining, pure white, are deposited on the bare loose decayed wood, and are from five to seven in number.

Besides the laughing note, which is repeated more frequently and loudly before rain, a low jarring sound is uttered by the adults, and is supposed to be a sexual call. Mr. Yarrell states that the young are fledged in June, and creep about at a short distance from the hole where they were hatched before they are able to fly, and that he has known the young birds taken from the tree and brought up by hand to become very tame and utter a low note not unlike that of a young gosling.

After the first moult the red on the top of the head disappears, to give place to the black; and the occiput, which is black in the young, becomes red in the adult males. By this peculiarity in the change of the livery the species is easily distinguished from those of _Picus leucogaster_ and _Picus medius_.

**Geographical Distribution.**—Extensive, more so, perhaps, than that of any other European Woodpecker. Denmarks Norway, Sweden, and Russia, Europe generally to Italy inclusive. Common in Scotland and Ireland. England, (rarer northwards), Scotland, Ireland.

**Habits.**—Food, &c.—Mr. Gould observes that the group to which this species belongs, although they occasionally depend to a great degree, and are also known and studied their habits and manners as the Great Woodpeckers represented by the _Picus viridis_, _caniceps_, and several others from the Himalaya Mountains. 'They exhibit,' says Mr. Gould in continuation, 'great dexterity in traversing the trunks of trees and in the large decayed limbs in quest of larvae and coleopterous insects which lurk beneath the bark, and to obtain which they labour with great assiduity, disengaging large masses of bark, or so disturbing it by repeated blows as to disarray the objects of their search. Besides searching for the grubs of the higher glade is observed to alight upon rails, old posts, and decayed poles, where, among the moss and vegetable matter, they find a plentiful harvest of spiders, ants, and other insects; nor are they free from the charge of plundering the fruit-trees of the garden, and in fact commit great havoc among cherries, plums, and wall-fruit in general. Their flight is rapid and short, passing from tree to tree, or from one wood to another, by a series of undulations. In their habits they are shy and reticent, and so great is their activity among the branches of trees that they seldom suffer themselves to be wholly seen, dodging as so to keep the branch or stem between themselves and the observer.'

**Birds of Europe.**

The editor of Pennant's _British Zoology_ states that this species puts the point of its bill into a crack or the limb of a large tree, and makes a quick tremulous motion with its head, thereby occasioning a sound as if the tree was splitting, which alarms the insects and induces them to quit the recesses: this, the editor says, it repeats during the spring in the same spot every minute or two for half an hour, and will then fly to another tree, generally fixing itself near the top for the same purpose. The noise, he adds, may be distinctly heard for half a mile, and he remarks that the bird will also keep its head in very quick motion, while moving about the tree for food, jarring the bark, and shaking it at the time it is seeking for insects. Bechstein says, that the food of this species consists of insects, beetle-mast, acorns, nuts, and the seed of pine and fir, and that in order to crack nuts, it fixes them in the elets of the trees. Temminck makes the food to consist of 'hametons (Melolonthae), bees, grasshoppers, ants, perforating and other larvae.'

The eggs, which are glossy-white, and from four to six in number, are deposited at the bottom of a hole in a tree upon the decayed wood.

Montagu gives a strong instance of the pertinacity with which the female remains at her duty. It was with difficulty that the bird was persuaded to quit her eggs; for notwithstanding a chisel and mallet were used to enlarge the hole, she did not attempt to fly out till the hand was introduced, when she quitted the tree at another opening. Montagu further states, that this species more frequently makes its nest in the woodpeckers are distinguished, than either of the others, especially when disturbed from the nest, as he had
an opportunity of observing on the occasion above mentioned. 'As soon,' continues he, 'as the female had escaped, she flew to a decayed branch of a neighbouring tree, and there began the jarring noise before-mentioned, which was soon answered by the male from a distant part of the wood, who soon joined his mate, and both continued these vibrations, trying different branches, till they found the most sonorous.

It is an observation of Mr. Selby's, that scarcely a year passes in Northumberland without some of these birds being obtained in the months of October and November. This induces him to suppose that they are migratory in some of the more northern parts of Europe, perhaps in Norway and Sweden. They arrive, he remarks, about the same time as the Woodcock and other equatorial migrants, and generally after stormy weather from the north or north-east.

The favourite localities of the Greater Spotted Woodpecker are large woods and well-timbered parks. It has been seen, but not so abundantly as the next species, in Kensington Gardens.

Pennant and others have placed the Middle Spotted Woodpecker, Picus medius, among the British birds; but there is no safe record of its having been ever seen in this country. The mistake has arisen from the capsus being the crimson-headed portion of the Greater Spotted Woodpecker to be the Middle Spotted Woodpecker, which, when in perfect plumage, has the top of the head red. The last-named species is now withdrawn from the British catalogue.

The Greater Spotted Woodpecker, Picus major, Linn.

Description.—Old Male.—The whole of the forehead, region of the eyes, sides of the neck, and under parts, a light rufous white; five longitudinal black lines on the face, two on each side; and the top of the head and upper part of the back and wings black; on the rest of the under parts black and white bands; a black hand goes for the angle of the bill on the sides of the neck; lateral tail-feathers terminated with white and streaked with black; iris red, length of beak 5½ inches.

Female.—No red; white of the plumage cloudsied brown, with a greater number of spots and black spots in the male; the black of the upper parts is also perfect.

Varieties.—Pure white; yellowish-white with the black of the plumage weekly developed; sometimes ranged with white feathers.

This is Le Petit Epithète and Le Petit Pic of the French; Picchio sarto minor, Picchio piccolo, Picchio Cardellino, Picchietta Cardellinetto of the Italian; Pietzchen-Specht, Garten und Grau-Bunt-specht, Kleinere Junger, and Kleiner Baumhauk of the Germans; Kleine Konink, Specht of the Dutch; Lilla Hackspeltten of the Scandinavian Fauna; Lesser Spotted Woodpecker, Lesser Hackspelt, and Crow Bird of the modern British; Delor frith's of the ancient Britons.

Geographical Distribution.—This, the least of the European Woodpeckers, but by no means the smallest of the family, is pretty generally distributed over Europe and some portions of Asia, and as far east as Siberia, to India. It is common in England, and Sir Robert Sibbald claims it as a Scotch bird under the name of Picus varius minor, a designation by which it was known to Ray and the earlier naturalists. In Ireland it does not seem to have been noticed.

Habits, Food, &c.—Woods, orchards, nursery gardens, and well-timbered parks are the haunts of this pretty little bird. 'In England,' says Mr. Gould, 'it is far more abundant than is generally supposed; we have seldom sought for it in vain wherever large trees, particularly elms, grow in sufficient numbers to invite its abode. Its security from sight is to be attributed more to its habit of frequenting the topmost branches than to its rarity. Near London it is very common and may be seen by an attentive observer in Wimbledon, Kensington Gardens, and in any other park in the neighbourhood. Like many other birds whose habits are of an arboreal character, the Lesser Spotted Woodpecker appears to perform a certain daily round, traversing a given extent of district, and returning to the same spot whenever it befalls; in which it begins its operations, of which it is especially partial, it not unfrequently visit orchard-trees of large growth, running over their nogrown branches in quest of the larvae of insects which abound in such situations. In its actions it is very quick and alert. Unlike the large Woodpecker, which perches on the trunks of trees, it naturally frequents the smaller and more elevated branches, which it traverses with the utmost ease and celerity; should it perceive itself noticed, it becomes shy, and retreats from observation by concealing itself behind the branch on which it is seated, or by turning its tail so as to engage the extinction of its food, its attention appears to be so absorbed that it will allow itself to be closely approached without suspending its operations. When the time commences, it becomes clamorous and noisy, and its call becomes an often-repeated note, so closely resembling that of the Jay, and its presence is only betrayed by the reiterated strokes which it makes against the bark of trees.' (Birds of Europe.)

The four or five eggs are deposited in a hole in a tree, which is generally suited to the size of the bird, whereby larger intruders are excluded, and sometimes very deep. They are of a delicate flesh-colour before they are blown, but are so transparent that the colour imparted by the shell is visible, when blown they are of a shining white.

The Greater Spotted Woodpecker (Dendrocopos Major). Upperfigtv, male; lower, female. (Gould.)
Sweden, Russia, and Siberia forming its principal habitat; that it is also found among the Alps of Switzerland, is but an accidental visitor in France and Germany, and has never been taken, he believes, in the British Islands. Dr. Richardson says that this bird exists in all the forests of spruce-lying between Lake Superior and the Arctic Sea, and that it is the most common woodpecker north of Great Slave Lake. It much resembles, he adds, Picus ellioutus in its habits, except that it seeks its food principally on decaying trees of the pine tribe, in which it frequently makes holes large enough to bury itself, and remarks that it does not migrate. Temminck observes that the North American specimens are rather less and their colours more vivid than those of Europe; but the total length of a male killed near the sources of the Athabasca River (lat. 67°) is given by Dr. Richardson as nine inches six lines.

Insects and their larvae and wild fruits form the food of this species, which lays four or five pure white eggs in the hole of a tree.
vorous birds, says that there are other insect-eaters (serrulifer sometimes called the northern and lesser Pipra (Piciformes) of Aristotle’s text), and that some call both these Enocorax coromandus, that is, tree-pecker or piercer. These birds, he adds, resemble each other and have the same voice, but the greater has the loudest. They both obtain their food by flying to the trees and setting them alight. The Colius (eolien) and Colius (loleic), however, whose text is the only good one, also, which is the size of the Turtle-dove, but whose colour is green entirely. This, Aristotle says, is a great excavator of trees, on which it gets its living; and its voice is very loud. This bird especially occurs in the Peloponnesus. Aristotle then mentions another insectivorous bird, which is called Enocorax coromandus (eolienologia, grnat or insect catcher), and hollows trees; but this, from its small size and colour, can hardly have been any known Woodpecker. In the ninth chapter of the ninth book Aristotle states that the Dryocolaptes does best sit on the ground, but pecks the oak to make the worms and insects come forth, which it afterwards catches with its tongue, which is broad and large. It runs very quickly upon the trees.

This part of the description answers very well for a woodpecker, with the exception of the epithet ’broad’ as applied to the tongue. No known woodpecker has a broad tongue, and indeed the conformation forbids such a structure.

The rest of the description, relating to the strong claws for enabling the bird to fix itself against the tree and climb it, applies exactly to a woodpecker.

Aristotle mentions three of these Dryocolaptes, one smaller than a Cotyphus (black bird probably), which has red spots; a second of the same size as a Cotyphus; and a third not much less than a hen. It has its nest on trees, especially in the olive-tree, and feeds on enmets and worms which come out of the trees. To get at the worms he hollows the trees so much that, he remarks, care is to fall. A tame one having adjusted an almond in a chink of wood, broke it at the third stroke and ate the kernel.

Aristotle also mentions the strong and compact bill of the Dryocopus in the first chapter of the third book (De Plutius Anim). We have seen Belon’s opinion as to the Dryocopes; and he considers one of the Spotted Woodpeckers with red spots to be the Pipra. In his chapter on the ‘Pic verd rouge, nommé en Français Une Épeiche,’ he places above the cut the following synonyms:—'Pipra en Grec, Pipo et Picus martius minor in Latin, Épeiche, Cul rouge, ou Pic rouge en Français.’ (Folio, 1555.) In the 'Portraits d’Oiseaux' (1657) the same cut is superscribed ‘Grec, Pipra, Latin, Picus martius minor, Picus varius also printed in Italian, Greek, and French: ‘Épeiche, Cul rouge, Pic rouge.’ Beneath the cut are the following lines:

M. Camus is of opinion that the great Pipra is the Pic noir of M. Buffon, Picus martius; that the Colius en Pittius Anim and others, Picus viridis; and that the little Pipra is the Pic veri or Épeiche, Picus major.

Pliny appears to use the term Picus martius as a general name for all Woodpeckers. Thus, in the eighteenth chapter of his tenth book (Nat. Hist.), ‘De picis martio,’ he notices ‘pici, martio cognominis insignis’ as small birds with crooked claws, and proceeds to give a very fair account of their climbing and woodpecking habits, ‘scandentes in subretuum, selium modo,’ and their catching their young in the hollows. He who is entertained with Roman fable will find some amusement in Pliny’s pages where he speaks of these birds, which were highly esteemed in augury, especially in Latium, out of veneration to the mythical king from whom they derived their name. (Nat. Hist., x. 33; xi. 37; xxvi. 4; xxvii. 10; xxx. 16.)

Asiatic Woodpeckers.

Examples, Picus squamatus.

Description.—Top of the head and occiput scarlet; above and below the eye a yellowish-white streak; a black line extending from the base of the upper mandible to the sides of the neck; the upper surface of a bright green; quill-feathers and tail dull olive black, barred with white; throat and breast greyish-green; abdomen and under surface of a still lighter tint, marked with black scales densely and regularly disposed; bill yellowish-white, horn-brown at the base; tarsi brown. Length 12 inches.

Geographical Distribution.—Asia; the Himalaya Mountains.

Mr. Gould, from whom the above description is taken, observes, in his ‘Century,’ that there appears to be a natural group of the Woodpeckers, intermediate between the genus Colapes, whose habits confine them entirely to the ground, and the typical Picidae, who gain their subsistence almost wholly from the bark of trees. In this intermediate group we have Picus viridis and the Picus canus of the Continent considered as the types, and which are the only species found in Europe—the present species as well as Picus occipitalis, also a Himalayan bird, may be classed. All frequent trees as a resort for food, while at the same time they equally subsist, like the ground-feeding species, on nuts and other insects, which they obtain on the surface of the ground.

Mr. Gould further states that the locality of Picus squamatus as well as Picus occipitalis is believed to be confined solely to the higher parts of the mountains.

Picus Squamatus. (Gould.)

Picus Squamatus. (Gould.)

Picus Squamatus. (Gould.)

Picus Squamatus. (Gould.)
**Picus tigris,** Horst., an inhabitant of the Indian Archipelago, as well in colouring as in the absence of the hinder toe, which in both birds is represented only by a rudimentary tubercle.

Mr. Gould, who makes this observation, and from whose work on the Himalaya Birds the description is taken, remarks that it was the only one which the Hon. C. J. Shore, (through whose zoological researches in India the bird was first made known, and upon whom it was named) was able to procure. Few, if any, of the tribes surpass it in brilliancy of plumage.

**AFRICAN WOODPECKERS.**

**Example. Picus cafer (Genus Trachyphonus, Ranz; Orcipicops, Linn.; Polyiptite, Smith).**

This form, as we have already seen, has been arranged by Mr. G. R. Gray as the last of the subfamily Buceconinae.

**Generic Character.—** Bill of the length of the head, convex above, pointed, recurved or arched longitudinally, upper mandible thicker than the lower; nostrils oval, basal, furnished with bristles; tarsi slender; third quill longest; tail rounded.

The birds of this genus are Woodpeckers which seek their food on the ground, and under the bark and in the moss which grows on trees, and indeed the old zoologists termed the species which we have selected as an example a *Picus*. It differs however considerably from the typical woodpeckers, which has led to its separation, and the generic name applied to it by modern zoologists.

**Description of Picus cafer.** Head, belly, and rump yellow; upper covert of the tail orange; forehead black; two black smoky pointed aigrettes; a large black collar variegated with white, bordered above with a small narrow white edge, varied a little with brown below; back of the neck and back brown, each feather terminated with white. Tail rounded, brown, striped with greyish-white; bill black at the point.

This is the *Plumbeus* of Le Vaillant; *Trachyphonus* Voltzii, Ranz; *Micropteron sulphuratus*, Linn.; and *Polyiptite* guayaquil, Smith.

**Locality.** California. P. C., No. 1747.

**HABITS, FOOD, &C.—** This species inhabits the forests, and lives on insects and their larva which harbour in the moss that grows on trees and under their bark.

**AMERICAN WOODPECKERS.**

It is not to be wondered at that America, so rich in deep forests as it once must have been, and indeed is now where the axe of the woodman has not yet penetrated, should possess many species of Woodpeckers. Lawson thus enumerates those in Carolina known to him.

'Of Woodpeckers, we have four sorts. The first is as big as a pigeon, being of a dark brown colour, with a white cross on his back, his eyes circled with white, and on his head stands a tuft of beautiful scarlet feathers. His cry is heard a long way; and he flies from one rotten tree to another, to get grubs, which is the food he lives on.

'The second sort are of an olive colour, striped with yellow. They eat worms as well as grubs, and are about the bigness of those in Europe.

'The third is the same bigness as the last; he is pied with black and white, has a crimson head without a topping, and is a plague to the corn and fruit; especially the apples. He opens the covering of the young corn, so that the rain gets in and rots it.

'The fourth sort of these woodpeckers is a black and white speckled or mottled; the finest I ever saw. The cock has a red crown; he is not near so big as the others; his food is grubs, corn, and other creeping insects. He is not very wild, but will let one come up to him; then shifts on the other side of the tree from your sight; and so dodges you for a long time together. He is about the size of an English lark.'

Catesby notices the same species as Lawson and adds others; one of these, the Gold-winged Woodpecker, *Picus auratus* (Genus Colaptes, Sw.), appears to belong to the same genus as *Picus cafer* above noticed.

As examples of the North American species we select *Picus pilatus* and *Picus principalis*.

**Picus pilatus, (Genus Dryopoornus, Sw.).**

**Description.—Male.** Top of the head, occipital crest, and maxillary strip bright scarlet. Line bounding the crest laterally from the eye, a band from the nostrils to the side of the nape, thence along the neck to the sides of the breast, the concealed bases of all the quill-feathers, a spot covered by the spurious wing, the chin, throat, and lower body, is fringed with white. A bar across the orbit and to the middle of the nape, and the rest of the plumage pitch-black, purest on the quills and tail. Some of the ventral feathers are fringed with grey, and two or three of the greater quills are tipped exterally with brownish-white.

The female has a yellowish-brown forehead, with darker Vol. XXVII—32
shafts and a blackish maxillary stripe. Length of a male killed in the winter, lat. 57°, near the Rocky Mountains, 20 inches.

This is the Larger Red-crested Woodpecker of Catesby; Pileated Woodpecker of Pennant and others; Pileated Woodpecker or Log-Cock of the Anglo-Americans; Mok-hee-canneeses of the Cree Indians; Thëë-dile-thëë of the Chipewyan.

Geographical Distribution.—Not unfrequent in well-timbered forests, from Mexico to Canada, at least to the 50th degree N. (Nuttall). Resident all the year in the interior of the United States, from the thirty-sixth degree of latitude to the Arctic parallel; rarely appearing near Hudson's Bay, but frequenting the gloomiest recesses of the forests that skirt the Rocky Mountains. All the United States, and particularly numerous in the Gennesee country. in the state of New York, (Richardson.) Nuttall notices as singular, and perhaps showing the wild timidity of the bird, that though an inhabitant towards the savage and desolate sources of the Mississippi, it is unknown, at this time, in all the maritime parts of the populous and long-settled state of Massachusetts.

Habits, Food, &c.—Catesby says that these birds (besides insects which they get from rotten trees, their usual food) are destructive to 'maiz' by pecking holes through the husks that inclose the grain, and letting in the wet. Dr. Richardson says that the stillets of the crow-like bill which it frequents is often invaded by the stroke of its powerful bill, which excels the woodman's axe in the loudness of its sound, and still more in the rapidity with which it does its work. Inaccurately to express what is by far the most extraordinary feature of the Rocky Mountain Woodpecker, it is almost impossible to short in the quantity of chips it produces. Like other Woodpeckers, it is, he says, extremely industrious, seemingly never a moment idle, flying from tree to tree, and plying its head like a hammer the instant that it alights. A few strokes of the bill suffice to decompose the state of the tree; and Dr. Richardson concludes his observations on this species by remarking that if the bird judges that it would explore the interior of the tree, it instantly quits that tree for another.

The wood is filled with trees which cast their giant arms over all the uncumbered river lands may often be heard his loud, echoing, and incessant cackle, as he flies restlessly from tree to tree, presaging the approach of rainy weather. These notes resemble ekere rek rek rek, rek rek rek, uttered in a loud cadence, which gradually rises and falls. The marks of his industry are also abundantly visible on the decaying trees, which he probes and chisels with great dexterity, stripping off wide flakes of loosened bark, to come at the burrowing insects which chiefly compose his food; he has been shown engaging in that pursuit, and wildness and savagery govern all his motions; and by dodging and flying from place to place as soon as observed, he continues to escape every appearance of danger. Even in the event of a fatal wound, he will struggle with an unremitting resolution. He mast be removed from the trunk to which he trusts for his safety, to the very instant of death. When caught by a disabling wound, he still holds his ground against a tree, and strikes with bitterness the suspicious hand which attempts to grasp him, and, resolute for his native liberty, rarely submits to live in confinement. (Nuttall) further states that this species is without much foundation charged at times with tasting maize, but in winter he observed the bird in South Carolina occasionally making a hearty repast on a small piece of bread.

The female lays about six snow-white eggs in the cavity of a tree. Two broods are said to be produced in a season.

Picus principalis.

Description.—Black with a gloss of green. Fore part of the wings, the rest of the crest crimson, with some white at the base. A stripe of white proceeding from a little below the eye, down each side of the neck, and along the back (where the two are about an inch apart) nearly to the rump. Tall black, lapering from the two extremities of the head, and forming a single band. This stripe is three inches shorter than the middle ones, the feathers conceave below. Legs lead-colour. Bill an inch broad at the base, of the colour and consistence of ivory, and channeled. Tongue also white. Iris vivid yellow. Length about twenty inches; alar extent about thirty inches. (Nuttall.)

This is the Largest White-bill Woodpecker of Catesby; Ivory-billed Woodpecker and Large Log-Cock of the Anglo-Americans.

Geographical Distribution.—Brazil, Mexico, the Southern States, seldom seen to the north of Virginia, and rarely in that state.

Habits, Food, &c.—Catesby says that these birds 'winch chiefly on ants, woodworms, and other insects, which they saw out of rotten trees, Nature having so formed the bill, that it could be driven into a hole of four inches in diameter, and be holded by the middle. For the Spaniards call them Cucarones. He adds that their bills are much valued by the Ouac Indians, who make corncorns of them for their prized great warriors by fixing them round a wreath, with the points of the bills, for the summer season. None of these birds in their cold country, purchase the southern people at the price of two and sometimes three buck-skins a bill.

Nuttall states that it is a constant resident in the counties where it is found, in the treeless regions, even in the rainy season, and that the pair are believed to exist for life. 'More vagrant,' says Nuttall in conclusion, 'and independent than the rest of his family, he is rare found in the precincts of cultivated tracts; the scene of less remarkable is the two times, amidst trees of greatest magnitude. His reiterated trumpet note, what that similar to the high tones of the clarinet ('pait, pait, pait), is heard soon after day, and until a late morning, echoing loudly from the recesses of the攻克 trees, upon the tops of the hills, without showing any impartent or necessary desire to quit his native solitary abodes. Upon the giant trunk s moss-grown arms of this colossal of the forest, and staked by the stalwart, whose beak, the high rattleting clarion and repeated strokes of the princely Woodpecker are often the only sounds which vibrate through and communicate an air of life to the dismal wilds. His strident interrupted call, and his industrious blow that make the noisy scene of solemn grandeur, on which the mind dwells in a moment with sublime contemplation, convinced the there is no scene in nature devoid of harmonious existence. Nor is the performance of this industry, the loud chopings of his powerful bill. He is soon surrounded with striking monuments of his industry: like a reaper (a nick-name given him by the Spaniards), he is seen surrounded with cart-loads of chips and the unavailable mortar of the mass of bark which he has already divided from the coarser roots of the tall pine and cypress where he has been a few hours employed; the work of half a dozen men, falling trees in a whole morning, would scarcely exceed the pile he has produced in quest of a single breakfast upon a large tree which has already had the bark removed by the tree preparatory to his repeat. Many thousand of pine-trees in the Southern States have been destroyed in a single season by the insidious attacks of insects; and in the dormant state are not larger than a grain of rice. It is in quest of these enemies of the most imposing of the vegetable creation that the industrious and indefatigable Woodpecker exercises his peculiar labors. In the sound and healthy tree he finds nothing which serve him for food.

Wilson, whose 'American Ornithology' is known to every lover of the subject and of nature, wounded one of these birds. His narrative is painful. The Woodpecker did not survive his captivity more than three days, and he manifested an unequaled resolution and refinement of all sentimonts. When he was taken he uttered cries almost like those of an infant; and no sooner was he set alone for an hour, than he so worked, that he neatly cut a way through the wooden house in which he was held. He never made a hole large enough to admit natural ventilation, and sketched him, and died with unabated spirit. The unconquerable courage most probably gave the head and bill of the bird so much value in the eyes of the Indians. The four or five white eggs are generally laid in a hollow, at the base of a cypress or other large tree, on the underside of the trunk, at which both the male and female have laboured, to enlarge and fit it for the purposes of incubation, till it is some two or more feet in depth. About the middle o
June the young are seen abroad. Besides the usual arborescent insects, this woodpecker, it is said, is fond of grapes and other berries; but Indian corn, other grain, or any orchard fruit, it does not touch, according to good authorities.

As an example of the South American Woodpeckers we select:—

*Picus chilensis.*

Description.—Somber with little bars of brown and whitish except on the lower part of the back and rump, where a single colour predominates, forming a large patch of pure white; bill black; a grey hood, pencilled with very bright grey, covers the head; cheeks rusty, and throat whitish; all the upper part of the body, wings, and even the great quills, rusty brown barred with small whitish bands; shafts of the quills golden yellow, and their internal part fulvous brown, with a white border or a single spot of the same colour towards the middle; breast, abdomen, and flanks whitish, dotted with brown; colour of each feather yellowish-white, while the middle is occupied by a circle of brown deepest upon the breast. Tail-feathers stiff and wedge-shaped, brown above with a slight fulvous tint brightest below; the two external and the two internal ones are pencilled with whitish sinuous bands upon their edges. Colour of the tail greenish; that of the claws approaching reddish. Total length more than eleven inches. (Lesson.)

Locality.—The woods of the province of Concepcion at Chile. M. Leson killed many individuals upon the peninsula of Talcahuano.

The Chilians call this bird *Carpantero,* a name generally applied by the Spaniards to the woodpeckers, both in Europe and America.

No woodpeckers appear to have been found in Australia nor in the South Sea Islands.

**WOOD-PIGEON, one of the names for the Ring-Dove, *Columba Palumbus.* (COLUMBIDE, vol. vii., p. 37.)**

**WOOD-SORREL. [ONALIDACE.]**

**WOOD-SWALLOWS, a name given by the colonists of Australia to birds belonging to the genus *Artamus* of Vieillot: *Ocypterus,* Cuv.; *Leptopteryx,* Horst.; *Lanius,* Linn. They are the Swift Shrikes of Mr. Swainson.

Although ornithologists very frequently use Cuvier's generic name, *Artamus* has the priority, and, moreover, Cuvier's term had been pre-occupied to designate a genus of insects.

The genus has been generally arranged among the Swallows (vol. xxv., pp. 415, 416); but Mr. G. R. Gray, although he places it under the Dicrurinae, makes that subfamily the fifth and last of the Amphidiae.

Generic Character.—Bill gradually nched from the base, where it is very broad. Calummen thick and convex, without any ridge; the base dividing the frontal feathers and somewhat dilated. Rictus bishelled. Nostrils wide apart, naked, small, without a membrane, and pierced in the bill. Feet short, strong. Wings very long and pointed; the first quill longest. Tail short. (Swainson.)

**Geographical Distribution of the Genus.—India and Australia.**

**INDIAN WOOD SWALLOWS.**

Example, *Artamus leucorhynchos.*

Description.—Size rather larger than a sparrow, and in shape much more elongated. Head, neck, breast, back, wings, and tail black. Belly and upper part of the rump white. Under part of the wings (which are very long and reach at least an inch beyond the tail) grey. Bill greyish, conical, and very strong, slightly curved at its extremity, and its base surrounded with stiff bristles directed forwards. Legs black.

This is the *Lanius leucorhynchos* of Gmelin, *Pigregische Dominiquina des Philippines* of Sonnerat, and *White-belted Shrike of Latham.*

Habits.—Sonnerat states that this bird flies with rapidity, poised itself in the air like the Swallows. It is, he adds, an enemy to the crow; and although much smaller, the wood swallow not only dares to oppose but to provoke him. The combat is long and stubborn, sometimes continuing for half an hour, and concludes with the retreat of the wood swallow.
the crow. Perhaps, says Sonnerat, the crow despises this too, for unless some one is listening it dares not approach, and avoids his strokes by his activity, darting away and returning as he sees his opportunity.

M. Valenciennes has published a monograph of the species in the *Mémoires du Mus.* (tome vi, p. 20).

**Austrian Wood Swallows.**

Mr. Gould, in the sixth part of his great and beautiful work on the *Birds of New Holland,* now in course of publication, has figured and described no less than six species of *Artamus.* Of these we select as examples, *Artamus sordidus* and *Artamus cinereus.*

*Artamus sordidus.*

**Description.**—Head, neck, and the whole of the body, a sordidus grey; wings dark bluish-black, the external edge of the second, third, and fourth primaries white; tail bluish-black, all the feathers, except the two middle ones, largely tipped with white; irides dark brown; bill blue, with a black tip; feet nearly lead colour. Sexes alike in colour, but the female rather the smallest.

Young with a dirty-white irregular stripe down the centre of each feather on the upper parts, and motled with the same on the under parts.

This, according to Mr. Gould, whose description is, in the *Sordidus Turkheim,* *Artamus sordidus* of Latham; *Cephaleris albovittatus of Cuvier,* Valenciennes, and Gould’s Synopsis; *Artamus lilatus* of Vieillot; *Artamus albovittatus* of Vigors and Horstfield; *Leptopteryx albovittata* of Wagner; *Beit-sheer of the Aborigines of the lowland district of the Australian mainland (central area); and the *Wilde* of the Aborigines of King George’s Sound.

**Geographical Distribution.**—Mr. Gould states, that no species of the Australian *Artamus* with which he is acquainted possesses so wide a range from east to west as *Artamus sordidus*; it being present in the whole of the southern portion of the continent as well as in Van Diemen’s Land. The extent of its northern range, he says, has not yet been satisfactorily ascertained, beyond the certainty that hitherto it has not been received from any colony north of the Derwent.

**Habits, Food, &c.**—The same observing and enterprising ornithologist observes that it may be regarded as strictly migratory in Van Diemen’s Land, where it arrives in October, the beginning of the Australian summer, and after rearing at least two broods departs again northwards in November. On the continent, he remarks, a scattered few remain throughout the year in all the localities favourable to the habits of the bird, the number being regulated by the supply of the necessary insect-food. In specimens from Swan River, South Australia, and New South Wales, present no difference, he tells us, either in size or colour; but those from Van Diemen’s Land are invariably larger and of a deeper hue, a variety which Mr. Gould attributes to the superabundance of food in that more southern and humid climate.

This species breeds from September to December, and the situation of the nest is very much varied. Mr. Gould saw one placed in a thickly-leaved bough near the ground, while others were in a naked fork of a tree, on the side of thebole of a tree, in a niche formed by a portion of the bark having been separated from the trunk. He describes the nest as rather shallow, of a rounded form, about five inches in diameter, and composed of fine twigs neatly lined with fine grass and down. He observed that the nests found in Van Diemen’s Land were larger, more compact, and more neatly formed than those on the continent of Australia. The eggs, which are generally four in number, differ in the disposition of their markings. The dull white of the ground-colour is decorated with dark greyish-brown spots, and some Mr. Gould found a second series of greyish spots appearing as if from beneath the surface of the shell. Medium length eleven lines, and breadth eight lines.

But the general habits of this bird are so interesting and in certain instances so peculiar, that we shall lay them before our readers in Mr. Gould’s own words:

‘This Wood Swallow, besides being the commonest species of the genus, must, I think, be regarded a general favourite with the Australians, not only from its singular and pleasing actions, but by its often taking up its abode and incubating near the houses, particularly such as are surrounded by paddocks and open pasture lands skirted by large trees. It was in such situations as these in Van Diemen’s Land, at the commencement of spring, that I first had an opportunity of observing this species; it then very numerous on all the cleared estates on the north side of the Derwent, about eight or ten being seen on a single tree, and half as many crowding one another on the same dead branch, but never in such numbers as to preserve the appellation of nester. The call of this bird is act independently of the other; each, as the desire for food prompted it,setting forth from the branch to capture a passing insect, or to soar round the tree and return again to the same spot; on alighting it repeatedly throws up one claw, and stretches one wing at a time, and spreads the tail oblique, prior to settling. At other times a few were seen perched on the fence surrounding the paddock, on which they frequently descended, like starlings, in search of coleopterous and other insects. It is not however in this state of comparative quiescence that this graceful bird is seen to its best advantage; neither is it that kind of existence for which its form is especially adapted; for although its structure is more equally suited for terrestrial, arboreal, and aquatic habits than that of any other species I have examined, it is the form of its wing at once points out the air as its peculiar province; hence it is that when engaged in pursuit of the insects which the serene and warm weather has sent from their lurking-places among the foliage to sport a higher region, these birds soak in the air, and where they display its greatest beauty, while soaring above in a range of easy positions, with white-tipped tails widely spread.

Another very extraordinary and singular habit of this bird is that of clustering like bees on the dead branch of a tree, for the purpose of clearing the branches; such an assembly has been observed by Mr. Gilbert, during his residence at Swan River, and I have given his account in his own words:— “The great peculiarity in the habits of this bird is its manner of depending itself in perfect clusters, like a swarm of bees on a dead and thickly-crowned tree, on the under side of the dead branch, while others of the flock attach themselves one to the other, in such numbers that they have been observed nearly of the size of a bushel measure. It is very numerous in the town of Perth until about the middle of April, when I missed them again until near the end of May, when I saw it in countless numbers flying in company with the common Swallows and Martins over a lake about ten miles north of the town; so numerous in fact were they that they deserted the water as they flew over it. Its voice greatly resembles that of the Common Swallow in character, but is no more harsh.”
Mr. Gould gives a representation on the plate which accompanies his description of this extraordinary clustering habit. The birds in the representation at once remind one of a swarm of bees.

**Artamus cineraceus.**

*Description.*—Crown of the head, neck, throat, and chest grey, passing into sooty grey on the abdomen; space between the bill and the eye, fore-part of the cheek, chin, upper and under tail-covers jet black; two middle tail-feathers black; the remainder black largely tipped with white, with the exception of the outer feather on each side, in which the black extends on the outer web nearly to the tip; wings deep grey, primaries bluish-grey; under surface of the shoulder white, passing into grey on the under side of the primaries; irides dark blackish-brown; bill light greyish-blue at the base, black at the tip; legs and feet greenish-grey. Sexes alike in colour, and only to be distinguished by dissection. (Gould.)

This, the largest of the Australian Wood Swallows, is the *Ocypterus cineraceus*, Valenciennes; and also the *He-wa-wen* of the Aborigines of the lowland and mountain districts of Western Australia, and the *Wood Swallow* of the colonists of the same.

*Geographical Distribution.*—Timor and Australia. Range in the last-named country extensive. Found by Mr. Robert Brown at Broad Sound in the east, and by Mr. Gilbert on the west coast.

*Habits. Food, &c.*—Mr. Gould states that in Western Australia, although a very local, it is by no means an uncommon species, particularly at Swan River, where it inhabits the limestone hills near the coast and the ‘Clear Hills’ of the interior, assembling in small families, and feeding upon the seeds of the *Xanthorrhoea*, so that insects do not form the sole diet of this species. Mr. Gould indeed observes that with such avidity does it devour the ripe seeds of this grass-tree that several may be seen crowded together on the perpendicular seed-stalks of the plant busily engaged in extracting them; but he adds that at other times, particularly among the limestone hills, where the trees are few, it descends to the broken rocky ground in search of insects and their larvae.

The round nest is compactly formed in October and November, sometimes of fibrous roots lined with fine hair-like grasses, sometimes with grass-stems and small plants, and placed either in a scrubby bush or among the leaves of *Xanthorrhoea*. Mr. Gould remarks that it is deeper and more cup-shaped than those of the other members of this group. The eggs vary much in colour and the character of their markings. Bluish-white is the usual colour, spotted and blotched with lively reddish-brown, intermixed with obscure spots and purplish-grey dashes, the markings most numerous towards the larger end. (Birds of Australia.)
great demand for timber during the last war has greatly thinned them of their finest trees. When woods were abundant and covered a great portion of the land, little attention was paid to the increase or preservation of the trees; kings and lords of manors readily granted to their tenants rights of comminage, with the privilege of lopping the branches, always supposing them to be useless dead wood. The consequence of this is still to be seen in all old forests, which are now covered by the rooks, sparrows, which never found the fine trees enclosed or protected. The fine old trees, whose age can scarcely be guessed at, which are very picturesque objects and a fit study for the landscape-painter, have all evidently been topped, at some time or other, for the sake of the wood. For want of proper care, they have probably not been in such a state as would afford fine timber for shipbuilding. Windsor Forest, which has only been inclosed since 1813, affords many specimens of noble trunks now hollowed out by time and the admission of water from above, which might probably still be valuable, and which had they been duly protected, and only those branches carefully cut which were dead and showed decay. The dates of the inclosures of different parts of Windsor Great Park can be readily discovered by observing the forest of the oldest trees. In many extensive woods on private estates the want of care may be readily seen at the first inspection. Oak-woods are chiefly found in stiff clay soils, where the water is apt to accumulate, by which the roots are injured. The decay begins at the bottoms of the trunks and have attained their full growth. The water should be carefully let off by open drains and ditches, which should be regularly examined and cleared out every year before winter. The surface being thus kept dry, the timber, as well as the underwood, will grow more rapidly, and if not covered with the wood the will simply repay the outlay. Cattle should be carefully excluded from all woods; they destroy the young shoots by cropping them, and do much damage to the trunks. At the time when acorns and beechnuts are plentiful, pigs may be turned in without danger; for the acorns will turn up the ground in search of their food, and thus bury beechnuts and acorns, which may vegetate, and grow in time into fine trees; for it is well known that an oak raised in a nursery is always better and before than one which is raised in a nursery and transplanted in the woods; and the same may be said of beech raised from the seed.

The sweet chestnut is one of the most useful trees in a wood, provided it has room to grow. Its timber, when of a certain age, is as durable as oak, and the shoots which spring up from the old trunks cut down give the most useful and profitable coppice-wood. When it is recollected that a coppice may be cut advantageously every ten years, the calculation becomes still more profitable. If the timber after many years, it will be found that the wood, properly managed, pays fully as well as the timber. It is usual to cut down such trees as begin to show decay at top, when the coppice is cut; but it is better to anticipate this decay, and cut them when the money from such a tree year from year to year becomes as much as the interest of the money they would sell for amounts to. For example: Suppose that an oak standing measures fifty cubic feet, and with top, top, and bark, may be worth 10l. If it does not increase above two cubic feet in a year, it will not be profitable to let it stand, but if it be cut down others which interfere with the growth of its branches, its growth can be promoted, it may probably increase so much as to pay a good interest on its value. This is the case, in the case of a chestnut, when it would be much easier to cut. The time is a period when the increase of the wood in a tree is a maximum, and this depends on soil and situation. The head and branches contribute much to the growth of the trunk, and unless they have room to spread, the increase decreases in the part of the head. As the time for such a tree and for the branches begin to approach those of another tree, room must be made, by cutting out those trees which appear inferior in shape or in health. In the management of young plantations [Pl. 351], it is a question whether it is more profitable to cut off young trees at one time, or to let them arrive at their full size, which, for oaks, will take 150 or 200 years. The calculation is made on the annual increase of the wood, which is said to be greatest when the tree is about thirty years old. It has been often supposed that the slower a tree grows the stronger the wood will be; but this is a mistake, and some from one which, having been headed down as a pollard, had grown slowly, were tried by the action of a very powerful hydraulic-press, and the wood of the quicker growing trees showed the pressure much longer before it was broken or crushed.

Although it is generally on soils unfit for cultivation that plantations of wood are made, yet there are procl

mestic trees, chiefly oak, ash, and elm, according to the soil; and the landlord, having the benefit of their growth, only earns them when fit for sale. The tenant is scarcely aware of what the future rents of the estate will be, but he well knows, from experience, that he will pay a better rent than if it had been cultivated as a farm. On such land it is usual to plant oaks in the hedge-rows, where the trees, having room both for their branches and their roots, thrive well at the expense of the hedges. Most old farms consist of the trees, trees chiefly oak, ash, and elm, according to the soil; wood, and for a farm.

The time is a period when the increase of the wood in a tree is a maximum, and this depends on soil and situation. The head and branches contribute much to the growth of the trunk, and unless they have room to spread, the increase decreases in the part of the head. As the time for such a tree and for the branches begin to approach those of another tree, room must be made, by cutting out those trees which appear inferior in shape or in health. In the management of young plantations [Pl. 351], it is a question whether it is more profitable to cut off young trees at one time, or to let them arrive at their full size, which, for oaks, will take 150 or 200 years. The calculation is made on the annual increase of the wood, which is said to be greatest when the tree is about thirty years old. It has been often supposed that the slower a tree grows the stronger the wood will be; but this is a mistake, and some from one which, having been headed down as a pollard, had grown slowly, were tried by the action of a very powerful hydraulic-press, and the wood of the quicker growing trees showed the pressure much longer before it was broken or crushed.

The calculation is made on the annual increase of the wood, which is said to be greatest when the tree is about thirty years old. It has been often supposed that the slower a tree grows the stronger the wood will be; but this is a mistake, and some from one which, having been headed down as a pollard, had grown slowly, were tried by the action of a very powerful hydraulic-press, and the wood of the quicker growing trees showed the pressure much longer before it was broken or crushed.

Although it is generally on soils unfit for cultivation that plantations of wood are made, yet there are procl
the lime and brick kilns. Where old hedge-rows are cleared in the progress of agriculture, it is a common practice to give the stumps and roots found in old banks to the poor, for the trouble of grubbing them up and leveling the ground. This work is generally done in woods, and the wood is stacked into cords six feet long, three feet wide, and three feet high, and sold, in Berkshire, from 5s. to 7s. a cord: where coals are 30s. or more a ton, this is a great resource.

In France and other countries where they use chiefly wood for fuel, the trees which are preferred are beech-trees, which are allowed to grow very close in the woods, so as to draw each other up and form long thin stems. They are cut down when about thirty or forty years old, and are sold for firewood, except in forests where timber is raised for building, and with proper attention to the old woods, and by judicious plantations of new, timber may be yet raised to a much greater amount than it is, and without encroaching on the land devoted to the crops necessary for the increase of meat.

**WOODS AND FORESTS.** A considerable portion of the royal revenue consisted formerly of the rents and profits of the crown lands, which comprised numerous lordships and honours, together with forests and chases: from the principal source of profits lay in the fines or amerciaments levied for offences against the Forest Laws. [**Forests.**] The demesne lands which were retained by the king, or which came to the crown by forfeiture or otherwise, and were farmed out to subjects, were called the crown woods, and the lands held hereditarily in the woods were called the private woods. By an Act of 16 Geo. III. (altered by the 50 Geo. III., c. 65), an officer of survey-general of his Majesty's works and public buildings was created; but this and other officers are now incorporated with that of the Commissioners of his Majesty's Works, Land Revenues, Works and Buildings (2 Will. IV., c. 1, s. 1), who are commonly called the Commissioners of Woods and Forests, which office or board owes its present permanent shape to the statute 10 Geo. IV., c. 50 (amended and extended by 2 Will. IV., c. 1, s. 1). The Commissioners, who are not to exceed three in number, are appointed by letters patent (2 Will. IV., c. 1, s. 1). They are to make a declaration (5 & 6 Will. IV., c. 62, s. 2.) in lieu of the oath required formerly, 2 Will. IV., c. 1, s. 1. They are to have the principal direction of the principal works in the woods, and the duties of commissioners. Their salaries are fixed at 2000l. per annum for the chairman or first commissioner, and 1200l. for the other two (10 Geo. IV., c. 50, s. 11; 2 Will. IV., c. 1, s. 7). Only one of them is allowed to be on the board at a time, or by a resolution of the board in writing, the property therein still remains in the crown. (1 Q. B. Rep., 352.) They are required hereafter to observe all the orders and directions of the Lords of the Treasury touching the exercise of their powers (3 Will. IV., c. 1, s. 9).

The Commissioners have the power of appointing and removing various officers, such as receivers, surveyors, &c., whose salaries however are fixed by the Treasury (10 Geo. IV., c. 50, s. 12). They may also appoint stewards of the royal hundreds and manors to hold courts, and different penalties and forestal offices to preserve game, fish, &c.; and they may grant licences to hunt, fish, &c. (Id., s. 14).

They are empowered to grant leases of any part of the crown possessions for thirty-one years (10 Geo. IV., c. 50, s. 22); or, in case of houses, buildings, &c., or building- land (for ninety-nine years) to the Commissioners, which is not required to be for building purposes, and the leasing does not extend to the royal forests in England (Id., s. 25), except for the purpose of making railroads (Id., s. 97). The leases are required to contain certain specified provisions, and the lessors are not to be made dispensable in the event of breach of the lease. The Commissioners may refuse to grant any of the leases of the Commissioners, in leases for ninety-nine years (Id., s. 27). The leases are to be granted at a rack-rent, and no fine is to be reserved (Id., s. 28), except in building leases, in which a nominal rent may be reserved for the first three years (Id., s. 30), and a fine may be taken not exceeding one-third of the rent (Id., s. 31).

They may also sell any part of the crown possessions, except the forests (Id., s. 34), according to a mode pointed out (Id., s. 35), and all revenues arising from the sale of the crown lands, and the proceeds of any leases granted to the Commissioners, shall be paid into the exchequer (Id., s. 36). The Crown are empowered to give certain notices and claims to and authorize entries on land for breach of covenant, &c. (10 Geo. IV., c. 50, s. 92), and to compound, in certain cases, for rent (Id., s. 38).

Their accounts for public and audit purposes, and for the audit of the Forests, are kept under the 25 Geo. III., c. 62 (10 Geo. IV., c. 50., s. 19).

The receivers appointed by the Commissioners of Woods and Forests must be surveyors (Id., s. 60). They are required to account at stated periods to the Commissioners (Id., s. 81), and to transmit all sums received monthly (s. 84); and they are empowered to distrain for rent (s. 90).

Grubbing without the management of the crown lands is thus vested in the Commissioners, and the general power of alienation has been taken from the king, a power is reserved to the crown to grant sites for churches, chapels, and burial grounds, not exceeding five acres in extent, or twenty in value (10 Geo. IV., c. 50, s. 32); and by 1 & 2 Will. IV., c. 59, s. 1, churchwardens and overseers are empowered, with the consent of the Lords of the Treasury, to inclose a portion not exceeding fifty acres of any forest or waste lands belonging to the crown, lying in or near their parish, for the purpose of cultivating the same for the use of the poor.

Besides this general control over the crown lands, certain powers are given to the Commissioners which are referable to the execution of the Forest Laws. The powers and authorities belonging to the Crown in this respect are vested in the First Commissioner (10 Geo. IV., c. 50, s. 50); and the commissioners are also vested with powers to prevent and remove all unlawful inclosures, encroachments, &c., in their courts of attachment, and may impose fines upon the offenders (Id., s. 100), which may however be proceeded against by the ordinary course of law (s. 105). The verderers may appoint agents, under foresters and other officers of the forests and courts (s. 101), and may inquire into their conduct, and fine them for neglect of duty (s. 102).
Other penalties may be recovered before a justice of the peace (c. 16); and all such fines and penalties are to be applied to the expenses relating to the forests (s. 105).

As to the general revenue arising from the letting, &c., of the crown lands, the commissioners are directed to pay in the moneys received by them, to a proper account with the crown and Jegels, respectively (10 Geo. IV., c. 50, s. 117, 118) and the chartered banks of Scotland (3 & 4 Will. IV., c. 69, s. 17); and the annual income (after certain deductions) is to be carried to the consolidated fund (10 Geo. IV., c. 50, s. 113; 3 & 4 Will. IV., c. 69, s. 16). The transfer of the revenue arising from the crown lands to the consolidated fund is however the subject of a special arrangement between the crown and the subjects, terminating with the life of the king in whose reign it is made.

In 1652, c. 50, contains some provisions peculiar to Ireland. Leases, grants, &c. of any of the small branches of the royal revenue (s. 128), and the powers appertaining to the chancellor and council of the Duchy of Lancaster (s. 130), are exempted from its operation.

The real property of the crown may be thus classified:—

1. Honours, manors, and hundreds, not in lease.
2. Other lands in the occupation of the crown, either for the personal convenience of the king or for the public service.
3. Forests, chases and wastes.
4. Lands, tenements and hereditaments, held of the crown by lease.
5. Fee-farm rents, issuing out of lands, tenements and hereditaments, held of the crown in fee-simple.

With this 5th object, it would be impossible to attempt any particular enumeration: the fourth consisted, at the time of passing the statute 26 Geo. III., c. 87 (a.d. 1786), of about 130 manors, 52,000 acres of land in cultivation, 1800 houses in London and Westminster, and 450 houses in other principal towns; the buildings in town and in many places of worship belonging to the Methodists and Roman Catholics, who are not included in the foregoing number.

The second class comprises the following royal palaces and houses:—Buckingham Palace; St. James's Palace; the Pavilion at Brighton; Windsor Castle; the palaces of Hyde, Blenheim, and Whitehall; the Old Palace at Westminster; the House at Winchester; the palace of Greenwich (converted into a hospital for seamen); Somerset House (used as public offices); the palace of Westminster (Westminster Hall), including the houses of parliament and courts of law.

The following palaces and buildings have been pulled down and their sites used for other purposes:—Carlton House; the Mews; Newmarket Palace.

The following parks are also included in this class:—St. James's, Hyde, Bushy, Wimbledon, Hampton Court, Regent's Park, and Windsor.

In the third class are included not only the royal forests which have preserved their jura regalia, but several nominal forests and chases, warrens, wastes, &c. The following is a list of the royal forests:—In England; Windsor Forest; in Essex, Waltham Forest; in Gloucestershire, the Forest of Dean; in Hampshire, Bere Forest, New Forest, and the Forest of Wooton and Aldiechol; in Northamptonshire, Rockingham, Whittlewood, and Balsley Fields; in Nottinghamshire, Sherwood Forest; in Oxfordshire, Wychwood Forest.

There has arisen incidentally out of the proper duties of the department of Woods and Forests, since it was united with the Board of Public Works, the important office of providing for the people public buildings and collections. The duty of the state in this respect has only been recognised of late years, and perhaps we owe it to our intercourse with the Continent, and especially with France, that it has been at all acknowledged. It is not out of the question that 50 or 60 years ago Hyde Park and Kensington Gardens were the only public places of recreation open to the crowded and hard-worked population of London; since then, the improvements in those two places, and the formation of new streets and squares in those parts of the metropolis of which the land either belongs to the crown or has been purchased by parliament for public improvements, there have been opened the large gardens of St. James's Park and the Regent's Park; Primrose Hill, at the north of the Regent's Park, and a large piece of land at the north-east end of London, intended to be laid out as "Victoria Park," have been purchased for the public.

The palace and grounds of Hampton Court have been repaired and adorned, and have been thrown open gratuitously to the public, and the collection of pictures has been arranged and enlarged. For the zeal and taste displayed in these things, the nation is indebted to the department of Woods and Forests.

Woolwich. The municipal and customary borough in Oxfordshire, 62 miles west-north-west from London, and 8 miles north-west from Oxford. The town is situated on rising ground, on the east bank of the Gwyne, a stream which is expanded into a lake in Blenheim Park. It is in the parish of Woodstock and liberty of Woodford. The hamlet of Old Woodstock, though not included in the municipal borough, may be considered as forming a part of the actual town of New Woodstock.

The town contains many good stone houses, and the streets are sufficiently wide. The town hall was erected about 1766, at the expense of the duke of Marlborough, after a design by Sir William Chambers. It is a good stone building, with a piazza beneath it, which is used as a market-place. The greater part of the town is served by the Board of Woods and Forests.

The municipal borough, which was not affected by the Municipal Reform Act, consists of a mayor, high steward, recorder, four aldermen, and twenty-six common-council men, and is returned by the commoners with a term of six years. The number of electors who had polled at any time during the thirty years preceding 1832, was 249. By the Reform Act the parliamentary borough has been much extended, and, in 1601, included a population of 72,000, who returned six members to parliament. The number of parliamentary electors at the register in 1832-30 was 369, of whom 216 were householders and 53 freemen. In 1836-8 the 10th householders were 240, and the freemen 64, in all 304. The area of the town is about 1600 acres. The town is only, and is de jure, the city and corporation of Woolwich, and is de facto within the limits of the parish of Woolwich, in ratio 144.

There has been little change in the number of inhabitants for the last forty years.

Blenheim Park, the magnificent domain of the dukes of Marlborough and the seat of the freeholders of Blenheim (BLENHEIM PARK) (Boundary Reports; Municipal Reports; Population Returns, &c.).

WOODVILLE, WILLIAM, was born at Cuckestones. He served an apprenticeship to an apothecary, and afterwards studied medicine at Edinburgh, where he graduated in 1775. After studying some time in the medical schools of the Continent, he returned to Cuckestones, where he commenced the practice of his profession. He continued here five or six years, and then removed to London. Here he was appointed physician to the Middlesex Dispensary, and in 1792 he was elected physician to the Small-Pox Hospital. Having paid considerable attention to the plants yielding medicinal substances, in 1793, a large work, in four quarto volumes, intitled 'Medical Botany,' which consisted of a series of plates representing medicinal plants, and containing an
count of their natural history and uses. This work is imper- perfect both in the drawings and descriptions of plants, but it was a valuable work at the time it was published, and has led to the production of better works on the same subject. In 1789 Woodward completed the publication of a work entitled 'History of the Small-Pox in Great Britain.' This work was never completed, on account of the introduction of vaccination about this time by Jenner. Dr. Woodville had good opportunities of investigating the causes of this disease ('Natural History of the Small-Pox') but was never able to form a satisfactory opinion on the subject.

This work received and deserved applause, but met with immediate opposition on good philosophical principles by J. A., M.D. (Dr. Arbuthnot), 1697. The author however remained unconvinced, and published in 1724 a defence of his system against the objections of Camerarius of Bonn, (Naturae Historiae Antiquae). To this work Woodward appended a Classification of Earths, Stones, Salts, Bitumens, Minerals, and Metals (Methodica Fossilium in Classibus Distributio), dedicated to Sir Isaac Newton, Pres. R. S.). In 1728, after his death, appeared an enlargement of this method, containing many interesting letters to Newton, Horskyns, &c., and directions for observers and collectors. A greater and more valuable work, in two volumes, published from Woodward's MS. in 1805 (An Essay on the Natural History of the Fossils of England), closes the list of the geological publications of Woodward. The first volume of this catalogue contains notices of above 'fifteen hundred bodies' in the first part, and a catalogue of 'English extraneous fossils' in the second part, and those connected with the University of Cambridge, and are still preserved therein, according to the directions of the will, by the professors on Woodward's foundation. In the second volume are described additional English and some foreign specimens, which it is hoped will be so.

Dr. Woodward appears to have been diligent and accurate in gathering information, and tolerably versed in the philosophy and science of his day, but his hypotheses are little in harmony with chemistry or mechanics, and some of his ideas are opposed to the allusions to natural philosophy. The sincerity and zeal with which he prosecuted geology are evinced by the noble bequest of his collections, and a fund for endowing a professorship, to the University of Cambridge; a bequest which has given the opportunity for Mitchell and Sedgwick to enliven the University, and to link the name of Woodward with some of the highest and surest generalizations in geological science.

1707 he published 'An Account of Roman Urns and other Antiquities likely dug up near Bishopsgate,' addressed to Sir Christopher Wren, and in other respects he distinguished himself as a collector of antiquities. His professional career appears to have been prosperous. He was elected fellow of the Royal Society in 1724, and was appointed Professor of Physic in Gresham College. He engaged in controversy with Mead and Friend on the subject of small-pox. His death happened in 1728.

WOOD-WREN, the name of a micrometric warbler which visits us in the spring and departs in September.

Mr. Yarrell, after tracing the steps of its history as a British bird through the works of White of Selborne, Pennant, and Montagu, observes that the bird is now very well known, and is at once distinguished from the true trochilus, or Willow-Warbler, with which it is most likely to be confounded, by the broad streak over the eye and ear-coverts of bright sulphur-yellow, by the pure green colour of the upper parts of the body, and by the delicate unblushed white of the belly and under tail-coverts.

In addition to these distinctions, which, Mr. Yarrell observes, on comparing the two birds, will be found very obvious, he points out the fact that the wing of the Willow-Warbler is nearly an inch longer than the wing of this bird; that the tail of the Willow-Warbler reach only to the end of the upper tail-coverts, or less than half way along the tail-feathers. The two birds here named, and a third species, the Chiff-Chaff, so called from its peculiar note, are, Mr. Yarrell remarks, the only British species included in the genus Sylvia as at present restricted. These, he states, differ from the warblers generally in the colour of their plumage, and in not being fruit-eaters. Their nests, he adds, are covered of dry moss and a little creep into the hollow chamber within by a small round hole, generally left in the side.
The Wood-Warbler or Wood-Wren appears to be the Sylvia sylvicola of Pennant; Motacilla trochilus of Bewick; Sylvia sibilans of Bechstein; Carvus sibilans of Wool; Bee-finch sylvicola of Temminck; La Faunette sylvicola of Vieillot; Lui verde di Savi; Grüner Sanger of Meyer; and Schuerrender, Grosschäubiger, and Nordischer Laubvogel of Brehm.

Geographical Distribution.—A Swedish summer visitor, but rare there, as it is in northern Europe generally. Of frequent occurrence in Germany, Holland, France, Provence, and Italy, in the summer. England and Wales, but not recorded in Scotland nor identified in Ireland.

Supposed winter-quarters, Egypt and Asia.

Habits, Food, &c.—The song, if song it may be called, of this species is to be heard in the woodlands of England and Wales in the spring, and during the greater part of the summer, accompanied by a shriveling of the wings, which, as the observer, by a peculiar tremulous motion of the wings, which are lowered by the side. A lofty elm in a hedgerow is often, he observes with equal truth, selected as the singing station, and the note is occasionally uttered while the bird wings its way from place to place.

Insects and their larvae form its food, which is captured both on the wing and among the leaves of trees. The oval and domed nest is framed, amid the herbage on the ground, of dry grass, leaves, and a little moss, with a finer lining of grass and hairs, but no feathers, which last are present in the nests of other warblers that build on the ground, with the exception of the other two Sylvia noticed above. The white eggs, most thickly speckled with purple-red and ash, are generally six in number.

WOOL

WOOL Lying hidden beneath. The goals of Angora or Cashmere, of Tibet, and of Cashmere yield woolly fibres of great beauty, which not only equal those of the sheep, but greatly surpass them; this wool however, as we shall see further on, is too costly to come prominently into competition with that of the sheep.

In a commercial and manufacturing point of view, a notice of wool may consist of its place of origin, the breed of sheep; and for an account of the growth and qualities of sheep's wool, the attempts made to improve it, the counties in England and the countries abroad whence it is procured, and the process of shearing, very little more will be necessary than that a reference to the article Sheep (p. 362). The history of wool in its unmanufactured state, is regarded the legislative enactments to which the commodity has been subjected, forms however a distinct subject, and is full of instruction in reference to the principles and commercial economy. In all former times, the growth of just opinions on such matters, and the many conflicts by which these changes were wrought. Wool as an article of wealth has been singularly exposed to these contests; for the agriculturists and the manufacturer, as to the number of their protection; as to the sale abroad, as to the value of their produce to the manufacturer; and as to the price of their produce to the agriculturist. The reason which led the two great class interests to take opposite sides on the question, and the effects which that opposition had on the wool trade, will be seen from the following brief details, drawn chiefly from Smith (Memorials of Wool). Bischoff (History of Wool), M'Colloch (Commercial Dictionary and Statistical Account of the British Empire, and France), and Hume (Progress of the Trade).

In the time of Edward I. a duty was imposed on the exportation of British wool; and great complaints were made on his increasing the duty in 1296 from 2d. to 6d. per bag. Lynn, Newcastle, Kingston-upon-Hull, Bristol, Yarmouth, Ipswich, Southampton, and London were appointed ports from whence wool might be shipped, and at which customs-officers were appointed to receive the dues. When the king had terminated some of the wars in which he had been engaged, he lowered the duty to half a mark per hundred; but the high duty was again imposed at a subsequent period. In 1327 he gave of the first enactment for prohibiting the exportation of British wool, a measure coincident with the attempts of Edward II. to encourage the woollen manufacture in England. He consequently the same year obtained great rates of wool as the means of defraying the expenses of war; and the gross absurdity of his former restrictions could not be better shown than by the fact, that while he ostensibly prohibited the export of British wool, he sent his price quote for sale abroad, as he could thereby obtain a higher price than at home. Throughout the remainder of his reign Edward had frequent contests with the Commons and the merchants respecting his grants of wool, and a payable on wool sold, and the prohibition to export it. The customs being not confined to agriculturists and manufacturers, but between the king on one side and all the subjects on the other. By a statute of 27 Edw. III., the towns of Newcastle, York, Bristol, Lincoln, Gloucester, Canterbury, Exeter, Exeter, Caermathen, Dublin, Waterford, Cork, and Drogheda were appointed *staples* for wool, that is places where *alone* wool could be sold; *mayors* of the *staple* appointed to seal every sack of wool sold; a custom duty of half a mark per sack was charged to *denizens*; and ten shillings a sack to *aliens*; and the power of exporting was limited to *merchant strangers*, or to Home town merchants.

During the reigns of Richard II. and Henry IV., there were repeated *subsidies* of wool to the king, payable from towns concerning the places for the staple, alterations in the customs' duty, and *licences* granted to particular
parties in respect to exportation. The same indeed may be said respecting the next two reigns; but by the time of Henry VI. the 'merchants of the staple' appear to have acquired a kind of monopoly, which was often made a subject of complaint. Edward IV. enacted that no 'alien' shall alienate any of the royal manors or estates, and that no wool exportation is to be made to Calais; and in the next three reigns the policy pursued, however mistaken, seems to have arisen rather from a hope of encouraging woollen manufacturers in England than from the interest of the king. In the reign of Edward VI. the large import of English cloth, as the meagre wool profitable, began to inclose common lands as sheep pasturages with so much eagerness as to cause great complaints to be made; and this may perhaps be taken as the commencement of a new demand or protest, so far as the cultivators took up a position really or ostensibly opposed to the interests of the people. It was not however till the time of Charles I. that the absolute prohibition of exportation was determined on seriously; and this seems to have been, in the first case, not so much a demand by the manufacturers, as a source of revenue to the king by granting licences to favoured persons.

After the Restoration, in 1660, however, the prohibition became distinctly enacted; and, as Mr. M'Culloch remarks, 'from about 1720 to 1725, the export of wool was strictly prohibited.'

The consequences of this prohibition soon showed themselves. The wool-growers, shut out from a foreign market, suffered from diminution of price; all kinds of extravagant expenditure and dissipation followed; the 4th part of the income from the export of wool; a system of 'wool-running,' or smuggling, became very prevalent; and many pamphlets appeared from parties taking opposite sides of the question at issue. The agriculturists, thus restricted in respect to wool, insisted on the support of the Spanish Merino sheep, and on the making of maintaining their rents; this disturbed the course of trade between England and Ireland; and the attempts made at the instigation of the woollen manufacturers to compel the use of woolen goods excited the hostility of the Irish, and at length made the system become disarranged. For nearly a century after this enactment the prohibitory law ran counter to the interests of nearly all classes except the woolen manufacturers; and it is exceedingly doubtful whether even they derived benefit from it.

Smith, in his 'Memoirs of Wool,' has enumerated a vast number of pamphlets, published in the last century, of the following general tenor: from English wool-growers, to show that Irish wool ought not to be imported into England; or to the manufacturers, to show that the English wool ought not to be sent to foreign countries; from Irish graziers, to show that both of these restrictions were unjust; and from foreigners, to show that the non-exportation of British wool led to retaliatory measures on the part of the agriculturists, and that measures felt that the export was fitted by legislative measures thrown into antagonism; and there arose from time to time complaints on both sides. For instance, in 1725, the woolen manufacturers presented a petition to the House of Commons, in which they represented that 'in order to distinguish each grower's sheep feeding on common grounds, it has been the ancient custom to put a mark of pitch, tar, and other ingredients, capable of enduring the severities of the weather, upon some conspicuous part of the sheep; but of late years the hands have been so well on the sheep feeding on common as in inclosed grounds, with such excessive quantities of marking stuff, in order to increase its weight, that the manufacture has been rendered universally difficult, and too frequently unproductive should exportation be interdicted.' The worsted manufacturers were particularly vehement; for they had a notion, whether correct or not, that no other country produced long combing or worsted wools equal to that of Lincolnshire; and that if they could keep the whole of this wool in England, they might perhaps retain a monopoly of the worsted trade.

The union with Ireland, in 1600, was another cause of disagreement in the wool trade. By one of the resolutions of parliament preparatory to that measure, it was determined that the two countries should be placed on an equality, as regards foreign trade, and manufacturers of wool profitable, began to inclose common lands as sheep pasturages with so much eagerness as to cause great complaints to be made; and this may perhaps be taken as the commencement of a new demand or protest, so far as the cultivators took up a position really or ostensibly opposed to the interests of the people. It was not however till the time of Charles I. that the absolute prohibition of exportation was determined on seriously; and this seems to have been, in the first case, not so much a demand by the manufacturers, as a source of revenue to the king by granting licences to favoured persons.

After the Restoration, in 1660, however, the prohibition became distinctly enacted; and, as Mr. M'Culloch remarks, 'from about 1720 to 1725, the export of wool was strictly prohibited.'

The consequences of this prohibition soon showed themselves. The wool-growers, shut out from a foreign market, suffered from diminution of price; all kinds of extravagant expenditure and dissipation followed; the 4th part of the income from the export of wool; a system of 'wool-running,' or smuggling, became very prevalent; and many pamphlets appeared from parties taking opposite sides of the question at issue. The agriculturists, thus restricted in respect to wool, insisted on the support of the Spanish Merino sheep, and on the making of maintaining their rents; this disturbed the course of trade between England and Ireland; and the attempts made at the instigation of the woollen manufacturers to compel the use of woolen goods excited the hostility of the Irish, and at length made the system become disarranged. For nearly a century after this enactment the prohibitory law ran counter to the interests of nearly all classes except the woolen manufacturers; and it is exceedingly doubtful whether even they derived benefit from it.

Smith, in his 'Memoirs of Wool,' has enumerated a vast number of pamphlets, published in the last century, of the following general tenor: from English wool-growers, to show that Irish wool ought not to be imported into England; or to the manufacturers, to show that the English wool ought not to be sent to foreign countries; from Irish graziers, to show that both of these restrictions were unjust; and from foreigners, to show that the non-exportation of British wool led to retaliatory measures on their part. The agriculturists, thus restricted in respect to wool, insisted on the support of the Spanish Merino sheep, and on the making of maintaining their rents; this disturbed the course of trade between England and Ireland; and the attempts made at the instigation of the woollen manufacturers to compel the use of woolen goods excited the hostility of the Irish, and at length made the system become disarranged. gentlemen lb., and the attention of the government was repeatedly
directed to this matter, by the opposite statements of dif-
f erent parties. Finally, an attempt was made in parliament to
get the tax repealed in 1820, but without success. On March
13, 1821, the Earl of Liverpool made an announcement in
the House of Lords, in reply to petitions on the subject,
which is important as being perhaps the first distinct
authoritative recognition of those just principles which had
hitherto been neglected by both parties. Speaking of the
manufacturers, he said, 'It had originally been offered to
them, before the enactment of the new duties, that if they
themselves would agree to a free export of wool, their
value would be sufficiently recompensed.' What finally
resulted of this was, that the government would adopt a liberal
system on the one hand, if the manufacturers would do so on
the other. This was clearly the admission of an important
principle, which, if acted on earlier, would have saved
valuable reforms. But the wool manufacturers would not
accept the repeal of the tax at the expense of what
they seemed to think a greater evil—the free exportation
of British wool; and consequently the attempt fell to the
ground. Throughout 1820 and 1821, measures were held, speeches made, and petitions signed; and in the
following year Mr. Robinson (now earl of Ripon), after
alluding to the peculiar tinge of monopoly shown in the
arguments of both parties, proposed to admit the export
of British wool at one penny a pound, and the export
of foreign wool at an equal duty—thus showing to
both parties the same need of fairness. Neither party
seemed very well pleased with the proposal, but ministers
brought it before parliament, and carried it into a law.
In the year 1825, Mr. Peel appointed a committee of
the Lords, to examine witnesses in favour respectively of all the
four sub-parties (for the manufacturers were often alluded to
as being divided into the 'long-wool interest' and 'short-wool interest,' while the wool growers were in some cases the 'Merino interest,' and in others the 'South
Down interest'). The evidence taken before the com-
mittee appears to have convinced the government that it
would be wrong to re-impose duties on the import duties
as a protective measure; and there has not since then been any
renewal of the onerous duties.
Many of the legislative enactments here alluded to
depend evidently on some peculiarity in foreign wool which
fits into this picture; and this striking likeness is seen in
the evidence before the Lords' Committee in 1828,
where several eminent manufacturers stated that they
could scarcely find a sale for any woollen claths if made
wholly of English wool. This superiority in the Merino
wool led to a large demand for it, and the import duties
were in part of the wool imported in 1828
introduced the Merino sheep into England. He
produced a new breed by crossing the Merino with English
sheep, and tried to combine the good qualities of both.
But the wool never attained such excellence as to induce
the manufacturers to give a price adequate to the trouble
of rearing the sheep, and after some time the king pres-
ented his flock to various eminent graziers. In Mr. Bis-
choff's 'History of Wool' there are letters of so late a date as
1845, in which he mentions the object of which he
had the honour of presenting to the king his prize-winning
sheep. The Merino sheep presented to him by George III.:
by crossing Merino
rams with long-wool ewes, a breed had been produced
which yields a good carcase for the market and a good
fleece. There are two other cases where that the
importation of short or clothing wool, for which the Merino sheep
in its natural state is so valuable, has not been a proposed
object of attainment in these experiments.
The wool of the goat [Ancyra; Cashmere; Goat];
transplanted, as a material in the manufacture of shawls, has
been an object of some attention among naturalists and
graziers. In the articles just referred to, the nature of
this wool and the places of growth are mentioned; but
it is sitting here to allude to an attempt made to naturalize
in England the animals which yield this beautiful sheep
wool: the 'Transactions' of the Society of Arts is our au-
thority. About the year 1820 two agents were sent out
by the French government to Tibet, for the purpose of
bringing some of the shawl-goats to Europe. After many
difficulties, and a few of the goats reached Paris in 1823
from Mr. Tower, a gentleman of Essex, promoted two
rams and two ewes. These he tended carefully, and by
1828 his stock increased to 27, and in 1833 to more than
50. Mr. Tower had a shawl or two made from the wool;
but the quality yielded was not quite as small as to
render the attempt a failure in a commercial point of
view. Since then attempts have been made to combine
the Cashmere with the Angora, but we do not know with
what result.
A few statistical details may now be given to show the
nature and extent of the wool-trade, in respect both to
British and to foreign produce. These will be derived
chiefly from Mr. Bischoff's work, which, published in
1845, brings down the information nearly to the
present time. In the year 1823, Mr. Luceock estimated the quantity of
wool produced in England and Wales thus:

<table>
<thead>
<tr>
<th>Description</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Short wool</td>
<td>202,737 packs</td>
</tr>
<tr>
<td>Long wool</td>
<td>131,794 packs</td>
</tr>
<tr>
<td>Skin wool</td>
<td>56,705 packs</td>
</tr>
</tbody>
</table>

Mr. Hubbard's estimate for 1823 was:

<table>
<thead>
<tr>
<th>Description</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Short wool</td>
<td>129,917 packs</td>
</tr>
<tr>
<td>Long wool</td>
<td>263,847 packs</td>
</tr>
<tr>
<td>Skin wool</td>
<td>69,405 packs</td>
</tr>
</tbody>
</table>

A pack being equal to 240 lbs. It has often been as-}
tained that the attempts to improve the quality of
English mutton have deterioated the quality of the fine wool;
and this seems to be borne out by the numbers here given.
Mr. Bischoff gives a table to show the quantity of
foreign wool imported every year from 1741 to 1841. Th
e will condense to a quinquennial form, thus:

<table>
<thead>
<tr>
<th>Year</th>
<th>Import (tons)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1777</td>
<td>1,892,772</td>
</tr>
<tr>
<td>1778</td>
<td>2,062,628</td>
</tr>
<tr>
<td>1779</td>
<td>1,999,543</td>
</tr>
<tr>
<td>1821</td>
<td>2,054,103</td>
</tr>
<tr>
<td>1826</td>
<td>2,014,511</td>
</tr>
</tbody>
</table>

These numbers sufficiently show how prone Eng-
lish wool manufacture is, when left to itself, to deri
ve the use from foreign wool.
All the finer wools used to be brought from Spain
and Portugal, and in the 1783 the elector of Saxony imported into his domain
from few other countries, of which have had a surprising in-
fluence on the trade in wool. The Saxony Merinos, inter-
ed of degenerating, improved upon their Spanish progenet,
and the wool afforhed by them has almost driven Eng-
lish wool out of the English market. This may be shown thus:

<table>
<thead>
<tr>
<th>Year</th>
<th>Import (tons)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1800</td>
<td>1819</td>
</tr>
<tr>
<td>1826</td>
<td>1902</td>
</tr>
</tbody>
</table>

Wool imported from Germany 412,264 778,835 5,113,442 21,829,829
From which it appears that in 1800 the imports of wool
from Spain were 14 times as large as from Germany; whereas from Germany those of 1840 were 16 times as large as those from Spain, making a relative increase of
238 to 1 in favour of Germany in forty years.

Another table gives the proportions imported from 32
countries in different countries in nine successive years; by
which it appears that the wool from Germany has been
largest in most years. But of these countries there is no small proportion that may possibly
be grouped together, thus:

<table>
<thead>
<tr>
<th>Country</th>
<th>Import (tons)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spain</td>
<td>27,776</td>
</tr>
<tr>
<td>France</td>
<td>20,744</td>
</tr>
<tr>
<td>Austria</td>
<td>19,184</td>
</tr>
<tr>
<td>Russia</td>
<td>12,424</td>
</tr>
<tr>
<td>Australia</td>
<td>9,162</td>
</tr>
<tr>
<td>Portugal</td>
<td>8,577</td>
</tr>
<tr>
<td>Belgium</td>
<td>4,034</td>
</tr>
<tr>
<td>Sweden</td>
<td>3,536</td>
</tr>
<tr>

The value of English wool from 1741 to 1790 was from 6d. to 13d. in the lower price being in 1773, the highest in 1772, and the mean price in the same period was 9d. per lb. In 1791 to 1840 the price of South Down wool varied from 7d. in 1829 to 36d. in 1839; while that of Kent long wool, within the same period, varied from 9d. in 1826 to 24d. in 1839. Broad and indigo dyeing, if British wool were removed; the exports were 18,000 lbs. in that year, 280,000 lbs. in 1827, and nearly 5,000,000 lbs. in 1840; thus showing that both the imports and exports of wool have prodigiously increased, when the commerce in this article is considered.

WOOL-TREE, a species of Eriodendron, a genus of plants belonging to the natural order Sterculiaceae. The wool-trees are large trees, with a spongy wood which is used for little besides making canoes in the districts where they grow. The leaves are palmate, and the flowers are large, red, white, or scarlet, and rising singly or in clusters from the sides or tops of the branches. The calyx is naked, irregularly 5-lobed, with the lobes usually thin; the petals are 5, joined together, and are connected with the column of the stamens, the latter being joined together into a short tube at the base, and divided into 5 bundles at the apex: these bundles are filiform, and each bears 1, 2, or 3 linear or anfractuous anthers at the apex, which have the appearance of one anther, and are either adnate or orifice and style. There are six species of Eriodendron, five of which are natives of America, and one of Asia and Africa.

E. anfractuosum has versatile anfractuous anthers; leaves large. The plant is shrubby and has a straight, and more or less wrinkled trunk. There is a species of South America, called E. sessilis,

F. Samannia has versatile anfractuous anthers; leaves with 5-7 oblong, quite entire, acuminate leaflets; the petals obsoletly spathulate, covered with glabrous down on the outside. The flowers are cream-coloured and are seated on the tops of the branches. This wool contained in the fruit is called in Brazil Samannia, and is used for stuffing pillows, bolsters, beds, &c. It is found in Brazil near the river Yupura.

E. Jannomitorum has versatile anfractuous anthers; a jointed style; it is a large, acute, entire leaflet; the petals reflexed; the tube of the stamens thickened at the top and entire, with the filaments 1-anthered. This plant is a native of Brazil, in the province of Minas Novas. It has white flowers smelling very like to those of the jasmine, and is contained in the fruit 2-3 in any of the countries. It may be grown in this country with ease. They may be propagated by cuttings which will root freely in sand under a hand-glass, but the plants which are produced from seeds thrive best. They do not usually produce their beautiful flowers till they are a large size in their native countries; therefore it can hardly be expected that they should flower in this country.

(Wool's Miller.)

WOOL, WOOL, or WOOL, is the common name of the species of Reseda, a genus of plants belonging to the type of the natural order Resedaceae, to which the common mignonette belongs. The genus Reseda, from seco, to calm or appease, because it is applied as a fomentation to relieve pain, is known by the flowers possess-...
WOOL AND WORSTED MANUFACTURES.

The manufactures in wool and in worsted are so closely connected, in reference both to their past history and to the industrial arrangements involved in them, that it will be convenient to treat of them together. The wool, whether in the form of worsted or woollen materials, is essentially the same; and the processes of dealing with it, though in some respects different, are in others very similar. The wool, therefore, will be treated of first, and the worsted manufacture will be considered afterwards.

WOOLEN MANUFACTURES.

The woolen manufacture, although dependent on the sheep, is independent of the climate. The English climate, on the contrary, is neither too hot nor too cold to suit the sheep, which is not the case with the sheep of other countries. The sheep, therefore, is always well supplied with wool, and has no occasion to travel far in search of pasture. The wool, therefore, is always abundant, and the manufacture is always active.

The English climate is, however, very favorable to the growth of the wool, and the wool is of a quality which is not found in any other country. The wool is grown in the counties of Yorkshire, Warwick, and Lincoln, and is known as English wool. The wool is of a fine quality, and is used for making shawls, blankets, and other articles of dress.

The wool is also used for making linens, and is known as English linen. The linen is of a fine quality, and is used for making tablecloths, sheets, and other articles of dress.

The wool is also used for making cotton, and is known as English cotton. The cotton is of a fine quality, and is used for making muslins, linens, and other articles of dress.

The wool is also used for making silk, and is known as English silk. The silk is of a fine quality, and is used for making scarves, shawls, and other articles of dress.

The wool is also used for making hemp, and is known as English hemp. The hemp is of a fine quality, and is used for making sails, ropes, and other articles of dress.
measures were passed, either by parliament or by cor-
porations, tending to cripple the free spread of the trade
and manufacture. Ireland suffered severely by this mis-
chievous system; for after being compelled to give up the
exportation of cattle to England, and on account of the com-
plaints of the graziers, she turned attention to the growth
of wool; but this offended the English wool-growers; and
if Irish cloths were sent to England, this roused the oppo-
sition of the English clothiers; so that from about 1640 to
that period there was one continuous struggle in
Ireland to bear up against the selfish policy of England
in respect to wool and its manufactures.

Throughout the greater part of the eighteenth century the
manufacture steadily increased in England, especially in
the south of England, on account of the inventions in spinning-machine which gave the extraordinary
imperative to the cotton-manufacture, that of wool could have been thrown comparatively into the shade; but the application of improved machinery has since increased the power of
the woollen manufacturers in England a more healthy tone
than they exhibited at the end of the last century. In a subsequent
page we give a few statistical details illustrative of the extent
and localisation of the manufacture.

PROCESSES OF THE WOOLEN MANUFACTURE.

It has been after explained that the woollen manufac-
ture relates to such fabrics as require the use of short or
fleecy wool. This wool undergoes a very large number of
processes before it reaches the weaving-manufacture. A
piece of broad-cloth as a representative of this manufacture
generally, the following are the successive processes by which it is produced:

1. Sorting the wool. 10. Spinning. 18. Fulling.
3. Dyeing (when dyed 12. Winding. 20. Interspinning, etc.

About one-half of these, in the most improved forms of
processing, are effected by machinery; and the other half
by hand labor.

The sorting of the wool is the first operation, and is one
of much importance, since the quality of the cloth depends
greatly on a due admixture of different kinds of wool. Each
pack of wool contains many different qualities, acci-
dental to the selection of the material. After the sorting
and picking, the wool is washed and scoured; and the
or other circumstances; and much tact and discrimination are
called for in the separation. The sorter has to make his
selection in relation to the fineness, the softness, the
strength, the colour, the cleanliness, and the weight of the
wool; and it is a matter of great interest to these qualities he attributes
the wool into many parcels, which receive the names of—
prime, choice, superior, second, third, coarsest, etc. With respect to
fineness, Dr. Perry found that the finest fibre of the wool
was an average of 1/4 of an inch; while the coarsest is that of Wilts.s, measuring
1/2 of an inch. All woolly fibres are thicker at one end than the other; but the less the difference in that respect, the more valuable is the wool. England, on account of the
strong points in Merino wool. According to the kind of good to be made, so do the several qualities in wool require to be studied; and hence the importance of the wool-sorter's
occupation.

When the proper kinds are selected, they are next
washed or scoured, to free them from the grease which in-
variably attaches to them. The wool is soaked in a lea of
steam line and soap at a temperature of about 180°, and
afterwards rinsed with cold water. In large manufactories the
wool is passed between the rollers of a powerful press
and scoured, to free it from nearly all moisture.

If the cloth is dyed in the wool, that operation succeeds
the scouring; but if dyed in the piece, many other pro-
cesses intervene; and it depends a good deal on the kind of
colour as to which plan is followed. Supposing the dye-
ting to be completed, however, the wool undergoes the pro-
cesses of 'willing' or 'wilting,' which is somewhat ana-
logous to the 'batting' or 'scutching' in the cotton-manu-
facture; the object being to open and disentangle the locks
of wool, and cleanse the fibre from seedy and other loose
impurities. The most improved machine for this purpose is that made by Mr. Lilly of Manchester, which acts in the following manner:—The willy is a kind of hollow trun-
cated cone, having an axis running through its centre; on
this axis are fixed a number of wheels of metal, each wheel
bearing on its circumference four longitudinal bars studded
with sharp spikes. The cone revolves with a rapidity of three or four hundred revolutions per minute,
within an outer cylindrical casing, whose inner surface is
streamed with a solution of soap and water. The mass of
an endless apron, with wool, which enters at the small
end of the cone, and travels to the larger end by virtue of the
centrifugal force produced by the rotation. As it passes onwards between the process the spin wool becomes
opened and disentangled, the fibres are then so'd and lock separated, and the impurities detached. But this is not all. When
the wool has reached the lower end of the cone, it passes
into a receptacle where a fan is revolving with great rapi-
dity, by which a current of air is generated strong
enough to blow away all the dust mixed with the wool; while at the
same time a kind of revolving cage distributes the wool in
a fine flat layer or stratum. Thus the same machine
disentangles the fibres, separates the impurities, blows them the dust, and arranges the wool in a
justly to work and against each other; the wires on one
cylinder are bent in a direction contrary to those in the
adjoining one; so that when all the cylinders are revolving,
and wool is applied to the first cylinder, it is thrown from
tooth to tooth, carried rapidly from cylinder to cylinder, separated completely from all entanglement, and finally given
forth in the shape of a delicate fibrous or sheet. It becomes wound on a revolving roller, or spinning-pot, or
spinning-wheel, it is as a carding-machine; but when it leaves the carding-machine it presents the appearance of slender rods, cylinders, or
pipes, which are called cardings.

These cardings are then spun into yarn for the use of the
woollen-weavers. This spinning being generally effected by means of the stubbing-billy or stub-
bing-machine, and afterwards by the common jenny or
mule-spinning machines; the stubbing-billy bringing the
wool to the state of a soft weak thread, and the spinning-
wheel giving it the proper firmness and hardness for
yarn. The following will give an idea of the appearance
and mode of action of the stubbing-billy, as described by
Dr. Ure: A is a wooden frame, within which is a move-
able carriage DDR, running on lower sides 2 and 3, on a
number of steel spindles, such as 1, 3, which receive a rapid motion from
a long cylinder, by means of separate cords passing round the
pulleys of the respective spindles; this cylinder is a
long drum of tin plate, six inches in diameter and the
whole breadth of the carriage. The spindles are placed in a frame so as to stand nearly upright at about four inches apart; their lower ends being so formed as to act as pivots. The drum enters the spindles with its centre a little horizontally before the spindles, or on the line of the spindle-pulleys. The drum
receives motion by a pulley at one end with an endless band
from a wheel E, which is placed on the outside of the
main frame, and which is turned by the power of the
horse at Q, who has his right hand applied to a winch; and by this
means the spindles are made to revolve rapidly. Each
Spindle receives a soft card or slubbing, which comes through beneath a wooden roller C C, at one end of the frame. A child is employed here, who brings the cards from the card-engine, and places them upon an inclined cloth between B and D. These cardings, being drawn beneath the roller, are then caught between two rails at G, and there held fast. The wire 7, the lever 6, and the wheel 5, are all concerned in the loosening of the carding from the rails at a particular period in the operation. The movement then is very similar to that in Har- greave's spinning-jenny; a small portion of each carding is allowed to pass between the rails or clasp; and this portion is then drawn out or elongated to the state of a thread by the recession of the carriage towards the other end of the frame. Meanwhile the spindles have been kept in motion, by which a slight twist is imparted to the thread or slubbing. The thicker wire 8, and the rail 4, assist in regulating the winding of the thread uniformly on the spindles. The process then is thus conducted: a child, called a 'piecer,' takes the cardings from the carding-machine, and lays them on the inclined apron; they are thence carried up beneath the roller and between the clasp, and the workman or 'slubber,' by managing his moveable carriage with one hand, and the wheel which turns the spindles with the other, elongates the 'carding' into 'slubbing,' and winds it on the spindles. The piecers are employed and paid by the slubber; and some years ago great cruelties were said to be inflicted on the children by the workmen for any neglect of their duty; but the inspectors of factories has removed such sources of discredit to the factory system.

In the spinning of the wool, which follows the slubbing, the kind of machines employed and the general character of the processes are so similar to those exhibited in the cotton manufacture, that it will suffice to refer to Cotton-Spinning and Spinning for details.

The process next following that of spinning is weaving, by which the yarn is worked up into a textile fabric. If it be a plain cloth, the loom employed is very simple in its arrangements; if it be a twill or an ornamental fabric, the loom is somewhat more complex; but the general arrangements will be sufficiently understood by a reference to Weaving. Hitherto woolen cloths have been principally woven by hand-weavers; but the power-loom is ever year becoming more and more applied to this purpose. Some of the cloths are woven as broad as twelve-quarters, to allow not only for the shrinkage occasioned in the subsequent process of fulling, but for an edging or 'list,' made either of goats' hair or of coarse yarn, into which the tenter-hooks are thrust in the process of tentering.

As the wool has been dressed with oil before spinning, and with size before weaving, it becomes necessary to cleanse it from these impurities immediately after the weaving.

This is the object of a second scouring process, in which the cloth is beaten with wooden mallets in a kind of vat or mill; soap and water being let in upon it first, and then water. Being then carried to the drying-mills, the calender-ground, it is stretched out by means of the calender-press, and then allowed to dry in the open air. It is then taken into a room and examined by hands who pick out all irregular threads, hairs, or dirt. And this it is ready for the important process of further fulling or felting, which imparts to woolen goods that permanent surface whereby they are distinguished from all other large mass of cloth folded into many plies is put into a fulling-mill, where it is subjected to the long-continued action of two heavy wooden mallets or stocks. Superficial part of the cloth has four fullings of three hours each, a third sort of soap being spread between each layer of cloth and time. During the violent peruscations which the cloth thus receives for twelve hours, the fibres, being at each stroke strongly impelled together, and driven into the closest possible contact, at length hook into each other the means of the little serrations on their surfaces, until they become firmly and inextricably united; each thread of the warp and weft, being so compacted with these are consequently to it, that the whole seems formed of one substance, not liable, like other woven goods, to unravel when cut with the scissors. The manner in which this compacting process the cloth manufacture is effected by beating, and the 'fulling;' in the hat-manufacture it is effected by pressing and rolling, and is called 'feltmaking;' but the two are now analogous in principle. This process thickens the cloth remarkably, but diminishes it both in length and breadth nearly one half.

In the fulled state the cloth presents a woolly and rugged appearance, to improve which it goes through the processes of teazling or raising, and shearing or cutting, the object of the first being to raise the ends of the fibres above the surface, and of the second to cut them off to a uniform level. The raising of the fibres is effected by thistle-heads, teazling-cards, or wire brushes. Teazling is the process of the driesseus fullum (Teazle), having small hooked points on their surfaces, which, by formerly used in the cloth manufacture thus: a number of these were put into a small frame with handles, and formed a kind of curvilinear comb, and were then passed horizontally, the direction of working being first parallel with the warp, and then parallel with the weft. From the trouble required to clean the bars of the teazles and

* Attempts have from time to time been made to produce a cloth fit for garments by the process of fulling only, without the aid of shearing; and some strength in the felt of a hat (similarly produced) would seem to answer well for such attempts. But hitherto the encouragement given to such as to render the project commercially successful,
filled with woolen fibres, from the weakening of their points by the water with which the cloth was saturated, and from the high price which the large demand enabled them to command in the market, numerous attempts were made from time to time to substitute metallic points; but we believe that from various causes the tealies are still preferred, and are now used in a more efficacious way than formerly. The tealies are arranged on a cylinder in a machine called a ‘gig-mill’; the cloth is stretched on two cloth-beams; the cylinder moves in one direction and the cloth in another, and the fibres become thereby worked or

combed up. The annexed cut shows the section of such a machine; where the cloth, passing from a roller $h$, round the roller $i$, comes in contact with the brushes $c$ on the wheel $a$, and afterwards passes round $g$ and $f$ to the roller $j$, the roller $i$ being so regulated by the pinion $n$ and the rack $m$ as to keep the cloth thoroughly stretched; and the revolving brush $j$ being so adjusted as to clean the teaing-cards $c$. In some recent machines the teaing-points are made of wire, to obviate the waste of 3000 natural tealies, which takes place in the dressing of one piece of cloth; but still the old tealies seem to maintain their supremacy.

When the ends of the fibres have been thus raised to the surface, they are next sheared or cropped, a process of great beauty and singularity. Originally this process was performed by means of large hand-shears, the cloth being stretched over a stuffed table, and the workman proceeding to clip the ends of the fibres in a regular and equable manner. This was an operation requiring great dexterity, and the men who worked at it, being in the receipt of good wages, were so alarmed at the introduction of shearing machines, in the early part of the present century, that serious riots occurred in the west of England. But the machines became by degrees extensively employed. They consisted each of a pair of shears, as in the hand-method; but all the movements were effected by machinery. More recently a machine has been introduced whose action is regulated on a different principle, as will be seen from the annexed cut: $b b b$ are disk-formed cutters, working against a thin bar of steel $a a a$, of a semi-circular form; which cutters, in their revolution travel round against the edge of the bar or blade in such a way as to shave off the filaments standing up on the surface of the cloth beneath. The cloth is acted upon by the shaded part. The wheel $c c c$, set in motion by machinery, imparts motion to the circular cutters attached to it through the medium of the rack $d d$. It is easy to see, that, where the machine travels along over the cloth, or the cloth travels along beneath the machine, every part of the fibrous surface is acted upon in precisely the same way by the double rotation of the wheel and the disk-cutters.

When the cloth has been raised and sheared (which operations are repeated two or three times for superfine cloth), it is brushed by a machine consisting of a system of brushes affixed to cylinders; the cloth being exposed at the same time to the action of the brushes and steam. A few subsequent operations are carried on, having for their object the imparting of smoothness, gloss, &c. to the cloth, preparatory to its being placed in the hands of the dealers.

A few remarks might here be made on the different kinds of goods coming under the denomination of ‘woollen manufactures,’ but it will be convenient first to notice the chief

**Processes of the Worsted Manufacture.**

The long wools for worsted fabrics, not requiring under go the felting process, pass through a circle of operations different from those hitherto noticed; since the object in view is rather to lay the fibres in a parallel position than to twist and entangle them one among another. All combing-wools are longer in fibre than the clothing-wools, but they are subject to the division into ‘long’ and ‘short’ combing-wools; the long, varying from six to twelve inches in length, being used principally for coarse worsted goods, and the short, from four to seven inches, being used for hosiery and some other purposes.

After the wool has been sorted, washed, and scoured from the adherent grease, and dried in a heated room, it is carried to a machine called a ‘plucker,’ containing a pair of spiked rollers, by the action of which the wool is cleansed, separated, and the fibres straightened, preparatory to the process of ‘combing.’ In hand-combing, which, until modern times, was the only mode followed, and which is rather laborious work, the proceedings are somewhat as follow:—The comber is provided with a pair of combs such as are here represented, a comb-post to which to

**Cloth-shearing Machine.**

**Wool-Combs.**

attatch the combs, and a comb-pot or stove for heating the teeth. Each comb consists of two rows of steel teeth, $a$, one row longer than the other, inserted in a wooden stock or head $c$, from which protrudes a handle $d$, and sometimes a direction of the teeth. Some combs have three rows of teeth. The workman first heats the teeth of one of the combs in the stove, and fixes it in the post, teeth uppermost. He then takes a small handful of wool, consisting of about four ounces, sprinkles it with oil to increase the pliancy and ductility of the filaments, and works it about between his hands to equalize the oil on every part of the fibres. The comb then takes half the bundle of oiled wool, and dashes it on the upturned teeth of the comb, till it is all deposited there, and caught between the teeth sufficiently firm to be retained. The comb with its wool is placed, points downwards, in the stove; and the
comber next fixes the other heated comb in the comb-post, lays the other half of the bundle of wool on it, and places this likewise in the stove. When both combs with their supply of wool are properly warmed, the comber holds one of them over his knee with his left hand, while seated on a low stool, and with the other comb, held in his right hand, he combs the wool upon the first, by introducing the points of the teeth of one comb into the wool contained in the other, and drawing them through it. This is repeated till the fibres are laid parallel. The comber always begins by introducing the points of the teeth of one comb first into the extremity of the fleece contained in the teeth of the other, and he then advances deeper at each succeeding stroke, till at length the combs are worked as closely as possible without bringing the teeth in actual collision: this plan is followed to prevent the breaking of the woolly fibres by too powerful an action in the first instance. These fibres being laid parallel, the teeth of the second comb, which constitutes about one-eighth of the length of the fibres, is unfit for spinning into worsted, and is consequently applied to other purposes.

At a worsted factory in the north we saw a most efficient combing-machine, of which a portion is represented in the annexed cut. It consists of two wheels of large diameter, like the one here sketched, having wires placed round the circumference, parallel with the axis, and pointed at one end so as to act like teeth. A boy, sitting on the ground, strikes wool on the points of the teeth in one wheel, so as to make it adhere to and between them. The two wheels are then made to rotate, the distance between them being such that the teeth of the one can draw through or comb the wool lying on the teeth of the other. This is effected with great rapidity; and when the combing is completed, the top or combed worsted is taken off by a boy or girl in a continuous stream from the upper part of the wheel, while the * noils* or uncombed part is removed by another boy.

When the wool has been combed either by hand or machine, it is transferred to the breaking-frame, the object of which is to open out any fibres which may have escaped the action of the combs. In this machine the wool, passing between rollers, is exposed to the action of a kind of endless comb, travelling round two rollers distant from each other; and the arrangements as to relative velocities are such that the wool becomes somewhat drawn out as well as sheared parallel, and leaves the machine in the form of a roll or narrow belt.

The breaking being thus effected, the sliver of wool proceeds to a large bobbin or cylinder, round which it is tapped into a continuous roll. It is then passed a second time through a breaking-frame, having teeth finer and more closely set than the former. The soft woolly ribbon is then subjected to the action of a machine analogous in principle to the drawing-frame of the cotton manufacture; the object being to extend the length, diminish the thickness, and equalise the number of fibres of the sliver. Hitherto the woolly fibres are merely slightly coherent, without having any twist; but they are now passed through a roving-machine, preparatory to the process of spinning. The working parts of this machine are slightly shown in section in the annexed cut. The wool, carried on a cylinder A, whose surface is studded with points or teeth, another instance of the extensive application of the combing process in the long-wool manufacture. The wool, after being acted on by these teeth, passes between the pair of rollers B, where it is

It is pressed by the upper roller being urged downward by the weight C. Of these rollers the upper one is of wood covered with leather, and the under one of iron, covered at the points with the axis. D, and this latter is urged to rotate faster than the feeding-roller F, it necessarily follows that the sliver of wool becomes elongated to a size or still greater tenacity while passing between them, and it is thereby caught by a second pair of rollers E, kept in contact by the weight D, and as these latter still revolve more rapidly than the former, the sliver is still more elongated until its thickness is so small that the fibres can scarcely cohere. But in order to give them the requisite cohesion, they are slightly twisted by the bobbin and G, that beautiful contrivance which is so extensively adopted in the textile manufactures. One fork or leg of the rotating flyer G is hollow or tubular, and down the tube the delicately corded wool passes; then, by the spin, rotation of the flyer, the wool or roving becomes wound on the spindle of the bobbin concentric with the eye.

The straight or rectilinear motion of the roving while approaching the flyer, combined with the circular motion of the flyer itself, imparts a twist to the roving, sufficient to enable it to undergo the process of spinning. The spools of the worsted bobbins are so close a resemblance to that of cotton, as described in Cotton-spinning and Spinning, that a reference to those articles will suffice to convey a general notion of the process. When spun the worsted yarn is wound on a reel, and these reels being made into hanks of 560 yards each. These hanks receive denominations according to the number of them which go to a pound, and the yarn derives its name in like manner, thus: 'No. 24' yarn has 24 hanks to the pound. In instances where a single worsted yarn is wound on a reel, the hanks are tied up into pots; the pots are combined into bundles; and the bundles are made into bales of 240 lbs. each, ready for the market.

Here terminate the operations of a worsted mill, for the dyeing of the yarn, and the weaving into the various kinds of textile fabrics, lead us to other departments of industry.

[Dyeing; Weaving.]

**Varieties and Places of Woollen and Worsted Manufactures.**

When it is considered that woollen and worsted goods differ principally in the length of fibre, it is easy to imagine that many varieties may be produced, according to the extent to which this separation is carried out. The varieties too, in which the warp and weft threads are made to interlace, as explained in Weaving, naturally lead to the production of many different classes of goods. There are four conditions, viz. the length of fibre, the appearance of the fibre, the quality of the material, and the width or size of the piece. All these factors, combined, give rise to the innumerable and fancifully-named kinds of woollen and worsted goods. Blankets, flannel, stuff, Merinos, mousseline-de-laines (wool muslin), beavers, tamisies, shawlon, sox, muslins, camlets, lastings, bazaars, and a host of other names, some of which are now nearly or quite out of use, and are giving...
way to others, points to the diverse applications of long-wool in the production of woven fabrics; while kerseymeres and other names indicate distinctions in the felted-wool goods. But besides these diversities, there are others depending on various circumstances; such as the admixture of woolen with worsted, or of either of them with cotton or silk, in the same fabric; the dyeing of the material, sometimes in the piece, sometimes uniformly in the yarn, and sometimes in a party-coloured mode called 'clouding;' and the variety of processes to which they are subjected, by the fulling process; whereas kerseymeres is a twilled fabric, similarly fulled. Serge is twills, having worsted warp and coarse woolen weft. Blankets are made of very soft yarn, afterwards dyed and printed. Many varieties of coarse cloth are of analogous structure. Bombazens is a twilled mixture of worsted and silk; whereas Poplin is an untwilled mixture, showing more silk than worsted at the surface. Modern goods called Soarones and Ornaments are made of woolen, sometimes mixed with cotton, and afterwards printed. Stuff is made wholly of worsted; while Merino is a fine woolen twill, sometimes printed. The material called Cashmere, if properly so named, is made of the shawl-warp, and worsted weft, and the fabrics so called are made of sheep's wool. Cloth is a mixture of woolen warp with silk warp, and is generally printed. Mousseline de-laine was originally all wool, but is now frequently mixed with cotton, and generally printed. Norfolk or Huddersfield are the chief varieties of cloth exposed of wool and silk, something like challis, but without being printed. Crepe de Lyon is formed of worsted and silk; and Italian set of worsted only. These examples are only intended to indicate the sources of the varieties of worsted goods, for too minute a description of the varieties themselves would be nearly impossible. This is particularly the case in respect to Washcoatings, where fancy-woying adds another to the sources of diversity.

Various details have been given, at different times and in different places, respecting the distribution of these manufactories, in respect to the towns where they are carried on, and the goods produced at each; but the most satisfactory, perhaps, are those given by Mr. McCulloch, in the 'Statistical Account of the British Empire,' and from that work we shall follow the following order.

The West Riding of Yorkshire, the most important clothing-district in England, exhibits an area of nearly 40 miles by 20 occupied by clothing towns and villages. Leeds, Bradford, Batley, Huddersfield, Dewsbury, Ossett, Wakefield, and Dewsbury, are among the chief manufacturing towns. Mixed or coloured cloths are made principally in the villages west of Leeds and of Wakefield; white or undyed cloths are made chiefly in the villages occupying a belt of country extending from near Wakefield to Shipley. These two districts are largely the spun worsted required for the various manufactures. Stuff is made at Bradford, Halifax, and Leeds; and narrow cloths at Huddersfield. Saltburn furnishes broad-cloth and kerseymeres. In the neighbouring towns of Wellington, Denby Dale, and Elsecar, and among the villages called 'boddy mills,' employed in the manufacture of yarn from old woollen rags, which is used in the weaving of some coarse kinds of goods.

The West of England takes rank next to Yorkshire, and forms the chief district in the manufacture of stockings and similar goods. The counties of Devon, Somerset, and Cornwall, are the most important. The manufacture is carried on in a district called the Bottoms, and in other parts of the county; the town of Stroud being a kind of centre for the whole. There are more than a hundred woollen factories in Gloucestershire; besides the numerous villages of small houses inhabited by hand-loom weavers. Wilts, however, produces only fine cloths, at Bradford, Trowbridge, Westbury, Melksham, Chippenham, and the surrounding villages; while cloth of various kinds is made at Witton, Warminster, Hayti-

bury, and Calne. Taunton, Frome, Tiverton, and the surrounding villages constitute the Somersetshire clothing district. Devonshire and Dorset have little woollen manufactures.

There is another district as distinctly marked from the two just noticed as they are from each other: this is the Norfolk district, which was long the principal seat of the 'stuff' or worsted manufacture. Indeed the name 'worsted' is said to have been derived from the name of a place in Norfolk, though in later times we are not wanting those who refer it to Ostades, the name given to them by the early Flemish weavers. Bombazeens, crapes, camlets, and shawls have constituted the chief fabrics for which Norfolk has been celebrated; but the manufacturers in the West of England are not declining, chiefly on account of the absence of coal, which has caused a large share of the operations from both Norfolk and the West of England to be transferred to Yorkshire; and indeed it is said that none of the yarn now used in Norfolk is spun at Bradford in Yorkshire.

These are the three great districts engaged in the consumption of wool; to which may be added Leicestershire, where nearly all the worsted stockings are made, employing ten or twelve thousand stocking-frames. But besides these, there are minor articles of manufacture which seem to have become located in particular spots in various parts of England. Draggets and long-els, the latter of which were formerly much purchased by the East India Company, are made in Devon. Riding cloths are made at Modbury in Devonshire. Baize, which used to be made largely in Essex, is now chiefly made at Rochdale. Salisbury produces flannels; and Witney and Chichester blankets. Kidderminster, Wilt, Cirencester, Worcester, and Boston, are the chief towns of Worcestershire, and the cloths of the carpet-manufacture.

Coarse woollens and druggets are made largely at Kendal, Keswick, and Ambleside. Druggets, shalloons, and sergees are made at Andover, Basingstoke, and Alton; worsted shag at Banbury and Coventry; rugs at Burford; feesby and Goodworth at Godalming; bunting and crapes in many parts of Suffolk.

In Wales the principal manufactures relating to wool and worsted are 'strong webs' or 'high-country cloths,' 'small webs' or 'low-country cloths,' flannels, stockings, wools, wigs, and gloves; the chief counties being Montgomery, Merioneth, and Denbigh. The 'strong webs' are used principally for workmen's jackets, ironing cloths, &c.; while the 'small webs' are largely used for slaves' clothing in the West Indies.

In Scotland the fine woollen manufacture is upon a limited scale; but a good deal is done at Aberdeen, Stirling, Galashiels, Jedburgh, Hawick, Inverness, Kirkmarnock, and Paisley, in the production of various kinds of woolen goods, for home consumption, passing under the name of 'polo-garn,' 'low-country cloths, worsted goods, and some plaidings, clan-tartans, woolen hose, blankets, flannels, and especial kinds of shawls. The manufactures of woollen and worsted goods in Ireland, owing to the unsettled state in which that country has unfortunately been placed, are quite insignificant.

**MODES OF CONDUCTING THE MANUFACTURE AND SALE.**

Different usages prevail in different counties respecting the connection between employers and employed, buyers and sellers, in the woollen and worsted manufactures. In the West of England the general plan of operation is this:—

The master-cluthier buys his foreign wool from the importer, and his English wool from the wool-stapler. He employs in all the different processes through which the wool passes in the course of manufacture, the whole number of persons, who sometimes work at their own houses, and sometimes in the factory of the master-cluthier. Each worker confines himself exclusively to a particular branch of the manufacture; and this has been supposed to have led to the exact distribution of the work in the West of England.

A second mode is on the factory-system, now extensively adopted in the West Riding of Yorkshire. The master-manufacturer, who sometimes possesses a large amount of capital, employs a great number of workmen in the various branches of the manufacture, from the grinding of flax to the finishing of the cloth, and also the managing of the carpenters and other services. In this system, as in the master-cluthier system, the workman has no property in the material on which he is employed.

In the domestic system, which was the original one adopted, the arrangement is altogether different.
this system the manufacture is conducted by a number of small masters, who are generally possessed of very limited capital, and who, besides their business as manufacturers, mostly occupy farms of a few acres, partly for the support of their families, and partly for the convenience of their manufacture. The domestic cloths in have in their houses from one to four looms, on which they employ themselves, their wives, and children, and perhaps other assistants. During their absence from work, their wives, children, and servants often take out into the fields to work. Formerly these cloths used to carry the wool through all the stages of its manufacture, till it was brought to the state of undressed cloth; but of late years they have united the two stages of quantity of public, which are established in and among the clothing-villages, for the performance of some of the processes; these mills having been erected on a joint-stock principle, by shares of 50l. or 100l. each, principally subscribed by the domestic clothiers, and also to be extensively employed in the woollen manufacture, in the early part of the present century, the domestic clothiers became violently excited, under the apprehension that their trade would be taken from them by the newly-invented machines. A Parliamentary committee inquiring into the probable operation of machinery in respect to the well-being of the domestic clothiers; and after examining numerous witnesses they made a Report, in which they detailed the distinctive features of the factory and the domestic establishment as to the difference of systems, instead of rivaling, are mutual aids to each other; supplying the other’s defects, and promoting the other’s prosperity. ‘Experience,’ says Mr. M’Culloch, ‘has proved the correctness of these conclusions. The number of factories and the manufacture of the woollen cloth produced by them, have both increased since 1806; but, as the number of factories, and the quantity of cloth made in them, have increased still more rapidly, the former constitute, at present, a less proportion of the trade.’

As respects the sale of the cloth, halls have been established for this purpose at Leeds, Halifax, Bradford, Huddersfield, and other towns, which are attended on the public holidays by thousands of the smaller class of manufacturers. The halls are divided into long walk or galleries, consisting of two rows of stands, each of which is marked with the name of the person by whom it is occupied. On these stands the cloth is exposed for sale; and when the markets open, the manufacturers take their stations at the stands behind their goods, the merchant-buyers passing to make their purchases through the avenues between the rows. The time during which the halls are open is limited usually to about one hour and a half; but in the intervals of the day, a very large number of buyers pass through them. There are two cloth-halls at Leeds, one for the sale of mixed cloth, containing 1800 stands, and one for the sale of white cloth, containing 1200 stands. These halls are appropriated exclusively to the use of those who had sold their cloths at the previous sales, and to the business of cloth-making; they are managed by trustees, and many of the stalls are the freehold property of the persons who occupy them. All the cloth sold in the halls is rough and undressed. Those by or for whom it is bought have what are termed ‘fittings-shops,’ where the cloth is shorn, dressed, and fitted for use. This is analogous to a system pursued by the bobbin-net manufacturers at Nottingham, where the net is sold by the maker in the rough state as it leaves the loom, and purchased by other parties, who singe, dress, and finish it ready for the net.

For the sale of various kinds of goods woven in North Wales there is a market held at Shrewsbury; but it is customary for the drapers of that town to travel into the country and buy goods wherever they find them. It is there usual also for the principal manufacturers to keep several at the greater part of the year, among the manufacturers, with whom they get acquainted, assist those who are poor with loans to purchase wool, and superintend the making and dressing of the goods. At Welshpool a flannel-market is held once a fortnight. To this market the manufacturers use to bring their goods; but now a set of middle-men go about the country, and buy all the flannels the manufacturers have to sell. At the Welshpool market nothing is sold on credit, every piece being paid for as soon as measured; and a similar system prevails in the other woollen markets of Wales.

**Extent of the Manufacture and Numbers of Operatives.**

The Custom-house returns enable us to form something like a correct opinion of the quantity of cloth which is manufactured in England yearly; but the amount of capital invested and the number of persons engaged have been very variously estimated. In 1778, the writer of a pamphlet on the subject of wool estimated the number of persons engaged in the woollen manufacture at 150,000, and their wages at 11,757,508l. per annum; this estimate was made by Dr. Campbell in 1774, thought that there might probably at that time be 1,000,000 persons employed in the manufacture in England, that the value of the wool used was 3,000,000l. per annum, and that this value was increased to 12,000l. per annum by the processes of manufacturing. In 1800 Mr. M’Culloch and Mr. Alexander, manufacturers, in committee before the House of Lords, made the extravagant estimate that there were 1,500,000 persons directly engaged in the manufacture, that the value of the wool used was more than 6,000l. sterling, and that of the manufactured goods 20,000,000l. per annum. In 1815 Mr. Stevenson reported that there were half a million persons employed, receiving 8,500l. per annum wages, and that the value of the raw material was 18,000,000l. per annum. Mr. M’Culloch (Statistical Account, vol. ii. p. 627) forms an estimate on the following grounds:

—That there are about 150,000 families engaged in the manufacture yearly; that this may be worth about 7,500,000l. that the value of the manufactured goods is three times that of the raw wool, making therefore 22,500,000l. per annum; and that this value is thus made up:

- Raw material 7,500,000l.
- Oil, soap, dye-stuffs, &c. 1,600,000l.
- Interest, profit, &c. 4,650,000l.
- Wages 8,750,000l.
- 22,500,000l.

And dividing this amount of wages at the rate of 52 weeks to each operative on an average, he arrives at the number 334,600, which he thinks a probable approximation to the number of persons employed in the whole manufacture in this country. Mr. Chapman (one of the Assistant Hand-Loom Commissioners, and the author of the able article on ‘Wool, and its Manufacture,’ in the new edition of the Encyclopaedia Britannica) makes an estimate in that treatise which agrees pretty nearly with that of Mr. M’Culloch; although at the first glance the two estimates seem discordant. He thinks that, in 1819, the number of families directly dependent on the manufacture were:

- In the West Riding of Yorkshire 85,696
- In the West of England 20,851
- In Norfolk and Kendall 17,570
- In the hosiery district 20,164
- In all other places 20,000

103,861

Then, taking the average number of persons in a family at 5, he arrives at an aggregate of 874,605 persons directly supported thereby. He further supposes that the number must have increased, by 1811, to 228,124,424 individuals. Mr. M’Culloch’s estimate is of the number of persons employed, while Mr. Chapman’s is of the number of persons supported; and this may explain the apparent discrepancy between the two estimates. To the number of the manufacturers proper, thus:—228,298 families, earning on an average 17s. 6d. per week each family, which amounts to 10,208,594l., and the relation between this and the other items of the table, thus states:

- Value of wool employed 10,000,000l.
- Oil, dye-stuffs, soap, &c. 1,500,000l.
- Wages 10,290,594l.
- Wear and tear, profit 4,353,311l.
- 22,500,000l.

We shall conclude with a few extracts from Mr. Bache’s tables. For about a century, from 1725 to 1830, all the cloths made and sold in the West Riding were

**WOO 556 WOO**
sured and stamped by officers appointed for that purpose; and from the returns made, it appeared that there were full, in the West Riding, the following number of pieces of broad and narrow cloth: the years named:

The woollens and worsteds exported in 1830, 1830, and 1840, or rather to January 5th in the following years, were as follows:

<table>
<thead>
<tr>
<th>Year</th>
<th>Wool</th>
<th>Spun yarn</th>
</tr>

<td>2,051,000</td>
<td>4,930,373</td>
</tr>
</tbody>
</table>

The most striking features in this table are the large increase in the exports of sheep's wool, spun yarn, and mixed wool and cotton fabrics.

In the parliamentary documents for 1842, the declared value of manufactured wool exported in 1841, independent of raw wool, is set down at £5,748,673. Of these exports there were sent to the United States the value of £1, 521, 987.; to Germany, £63, 676.; to the East Indies and China, £62, 710.; to British America, £5, 344.; to South America, £46, 074.; to Brazil, £29, 484.; and to Holland, £51, 695.; the other countries enumerated, twenty-three in number, having taken comparatively small quantities.

The importance of peaceable relations between this country and America is shown—in this, as in a hundred other instances—by the fact that one-fourth of all our exports in woollens, except those of the United States, are destined to that country. It is worthy of note that, in 1841, less than 7, 544,196 lbs. of British wool were exported to Belgium alone, out of a total export of 5, 471,235 lbs.

WOOLLIM, WILLIAM. This excellent engraver was born at Maidstone, in Kent, in 1725. He learned his art of John Tinney, an obscure engraver in London, but he soon adopted a style of his own, acquired early a great reputation as a landscape engraver, and was appointed engraver to George III. No artist ever used together more effectually the etching-needle and the graver: in foliage, water, and in rocks, Woollett was particularly successful, and is still unrivalled; but in figures, and especially in flesh, he was less so. In the latter part of his life Woollett took to histriography, and was also the engraver to whom some of the finest plates of the English school of engraving can boast: the Death of General Wolfe, and the Battle of the Hogue, both after West, are considered his best historical pieces, and they are certainly placed first in the panorama of his works. Of his landscapes his masterpieces are those which he engraved after Wilson: they are nine in number, namely, Phaeton, Niobe, Celadon and Amelina, Ceyx and Alcione, Snowdon, Cicero at his Villa, Meleager and Atalanta, Apollo and the Seasons, and Solitude, a companion-piece to Cicero at his Villa. In the last plate he was assisted by Ellis, and in the Meleager and in the Apollo by Poucney. He engraved also after Claude, Zuccarelli, the Smiths of Chichester, Stubbs, and others, and he executed some of Reynolds's portraits from life. Woollett died in London in 1785, aged 30, and was buried in old St. Pancras churchyard; there is a monument to him in the church of Westminster Abbey. He is spoken of as a man of admirable character, and a very amiable disposition. The following anecdote, said to have been told by West (Library of the Fine Arts, vol. ii.), evinces an extraordinary spirit of freedom and patience: Woollett, when he had finished his plate of the Battle of the Hogue, took a proof to West for his inspection: at first the president expressed himself perfectly satisfied and with the plate, but on conferring on the engraving, he observed that in some parts alterations might be made, and in others additional colour might be added, which, would, in his opinion, improve the effect of the plate; and taking a port-charge with black and white chalk in it, he examined the engraving, and reduced the work produced, remarking at the same time that it was of no great consequence, but it might improve the appearance of the plate. Woollett however immediately consented to make the alterations and additions pointed out,—But how long wilt it take you, Mr. Woollett? said the president. About three or four months, replied the engraver: and the patient creature, said West, when relating the circumstance, actually went through the additional labour without a murmur.

WOLSTON, THOMAS, was born in 1669, at Northampton, and was the son of a respectable tradesman of that city. He went from a grammar-school to Sidney Sussex College, Cambridge, where, after taking the degrees of Bachelor of Arts and Master of Arts, he was elected a fellow of his college, and afterwards entered into holy orders, and in due time took the degree of Bachelor of Divinity. In 1705 he published his first work, entitled ' The Old Apocalypse of the Christian Religion against the Jews, and entitled to receive the true interpretation.' This publication was followed by others from him till after an interval of fifteen years spent in laborious study of the works of the fathers within the walls of his college; and in the year 1720 he published three Latin tracts, one of which, entitled Res Jesu Christi gestas, per Mystagogum, was an endeavour to prove that the letter of Pontius Pilate which had been transmitted by the fathers was a forgery, without denying that a letter had been written to Tiberius; and the two others were entitled, In the name of the apostle and evangelist John, and Apologia, to Doctors Whitby, Waterland, and Whiston, on the interpretation of the Scriptures. About the same time he published two tracts, in the form of letters to Dr. Bennet, and under the name of Aristobulus, one on the question whether the Quakers do not the nearest of any other sect of religion resemble the primitive Christians in principles and practice? and the other being ' A Defence of the Apostles and Primitive Fathers of the Church in their Allegorical Interpretation of the Law of Moses, against the figure of the city of Jerusalem,' and ' Defences of the Apostles and Primitive Fathers of the Church, in their Allegorical Interpretation of the Law of Moses, against the figure of the city of Jerusalem,' and he immediately followed up these publications by writing an answer to them. The letters to Dr. Bennet, and the answer to the letters, abounded in attacks upon the clergy, which, together with the arguments for the interpretation of the letters, were prevailing as well the latter of the two letters, as his previous letters addressed to Doctors Whitby, Waterland, and Whiston, exposed Wolstton to much suspicion and attack from the clergy. His next publication, in 1722, was not calculated to give offence, being a tract entitled ' The exact Fitness of the Time in which Christ was manifested in the Flesh, demonstrated by Reason, against the Objections of the Old Gentiles and of Modern Unbelievers,' which had been written twenty years before. It was answered by William Whiston in 1723, and 1724 he published four pamphlets, under the title of Free Gifts to the Clergy, and then an answer to them, all directed against the clergy. In 1726 he entered into the controversy raised by Anthony Collins's Grounds and Reasons of the Christian Religion, and published two tracts; one of a work to which he gave the name of Moderator between an Infidel and Apostle, and two Supplements to the Moderator. The lengths to which he carried his allegorical interpretation of the Scriptures in these publications, denying the reality of the miracles wrought by Christ, brought upon him a prosecution by the attorney-general. This prosecution was stopped at the intercession of Mr. Whiston. Nothing daunted, he proceeded in 1728 in proclaiming his views as to the allegorical character of the miracles in ' Doubts on the Miracles of Christ,' which were addressed to six bishops—Gibson, bishop of London; Chandler, bishop of Lichfield; Smallbrooke, bishop—
of St. David's; Hare, bishop of Chichester; Sherlock, bishop of Bangor; and Potter, bishop of Oxford. In these discourses much was said against the clergy, and against the clergy in general, was mixed with the heterodox doctrine which they were wont to support; and the tone of ridicule and banter in which the miracles were treated of aggravated the offence given. Woolston was the object of detraction, and his defence, defended himself on his trial, was sentenced by the court of King's Bench to a year's imprisonment and a fine of £100. At the expiration of the year, being unable to pay the fine, he continued in confinement. Attempts were made by some of his friends to procure his release; but Woolston would not consent to give security not to offend again by similar writings. By the assistance of a brother, an alderman of Northampton, he was enabled to purchase the liberty of the rules of the King's Bench, and was partly supported by the public subscription, although the remainder of the fine was not paid. He had lost his fellowship at Cambridge some years before by non-residence. He died on the 27th of January, 1733, after a very short illness. He was buried in St. George's Churchyard, Southwark.

Royal Institution, a market-town in the county of Kent, on the south bank of the Thames, 8 miles below London by the road, 6½ miles by the river, which is there three-quarters of a mile wide. A tract of land in Essex, on the north bank of the Thames, is included in the parish of Woolstoum Green, and is 3 of an acre.

The town consists chiefly of a street nearly a mile long, on the bank of the river, with other streets diverging from it chiefly to the south. In this long street and the other streets immediately connected with it, which constitute the main centres of the town, many of the houses are old and small, and the arrangement of the streets is irregular and inconvenient, but in the higher and more modern part of the town there are several new streets of handsome houses. The streets are lighted with gas. The church is a plain building with a square tower: it is large enough to accommodate 1500 persons. The living is a rectory, in the gift of the bishop of Rochester, of the net annual value of £700, out of which £100 is paid to a curate. The Ordnance Chapel is on the road to Plumstead, and another chapel in the Royal Hospital is erected at both in the appointment of the Board of Ordnance. There are places of worship belonging to the Methodists, Baptists, Roman Catholics, and other classes of dissenters. There is a Mutual aid, a boarding-school, and a school under the patronage of the British and Foreign Bible Society.

The population of the town and parish of Woolstoum, in 1801, was 9,282; in 1811, 17,064; in 1821, 17,008; in 1831, 17,061; in 1841, 25,785, of whom 14,063 were males, and 11,722 females; of which return this includes the naval and military establishments. They were, in 1841, 3034 houses inhabited, 83 uninhabited, and 38 building. The following is the list of the government establishments, with the number of persons in each when the census was taken:

Royal Artillery Barracks, 2354 males, 506 females.
Royal Marine Barracks, 336 males, 70 females.
Royal Sappers and Miners' Barracks, 123 males, 33 females.
Royal Arsenal, 55 males, 101 females.
Her Majesty's Dockyard, 50 males, 49 females.
Royal Ordnance Hospital, 281 males, 12 females.
The hulks Warrior, Unit, and Justice, 1153 males, 12 females.

The population has no trade, except such as arises from the wants of the resident population.

The importance of Woolstoum has arisen from its Dockyard, from the government foundry for cannon having been established there, and from its having been made a great depot for naval and military stores. Of these and the other government establishments at Woolstoum the first was——

The Royal Dockyard, which was formed in the reign of Henry VII. The Harry Grace à Dieu, the largest vessel which has been constructed, was built there in 1515. The Dockyard was greatly enlarged and improved by Queen Elizabeth, and by Charles I. It now commences at the village of New Charlton on the west, and extends along the south bank of the river almost a mile to the east, very near to the Royal Arsenal. It contains two large dry dores, a basin 400 feet long by 300 feet wide, capable of receiving the largest vessels, extensive ranges of gun-sheds, storehouses, mast-houses, &c., and a large building provided with powerful steam-engines for manufacturing every article of iron used in the service, and capable of being made the largest. Each department is under the superintendence of a separate officer, and the whole under the direction of the Board of Admiralty.

The Royal Naval Gun foundry for casting cannon was formerly in Moorfields, and was removed to Woolstoum soon after a great explosion in 1716, occasioned by moisture in the moulds. Andrew Schalch, a young German founder, who had been allowed to look at the moulds, gave warning of the explosion, and, was he not Colonel Armstrong, surveyor-general of the ordnance, others to leave the ground; the operations proceeded with; the explosion took place, much damage was done, and several lives were lost. The government especially resolved to erect a separate building, which was done. The London, and Schalch, having been examined as to qualifications, was appointed to select a suitable place.

He chose the Warren at Woolstoum, the new work erected under his superintendence, and he was appointed Master-Founder for the purpose of it, which he held during sixty years. He died in 1760, at the age of 90, and was buried in the churchyard at Woolstoum.

The foundry for cannon forms one of the principal departments of the Royal Arsenal. It has four air-rooms, in which are the lathe and forging shops. In 1809, a year in which war was carried on with great activity, 385 guns were cast, and 343 in 1810. The air-rooms are cast solid, and bored and turned in a separate building: the gun is moved to round it, and upon being finished, is placed in a proper position for finishing the exterior is performed at the same time. The gun is ultimately proved by firing it on the靶, and in the case of the greatest guns, in the special range of the military range.

Another department of the Royal Arsenal is the Store-Room, which is near the foundry. It contains a plan or model of every article used in the artillery service: the machinery for grinding gun-powder, etc.; the store of iron, gun-cotton, shot, powder, and other ordnance material; and other articles of military manufacture are prepared. In other parts of the Arsenal are about three millions of cannon-balls and shot-shells, arranged in pyramidal groups.

The Storehouses of the Royal Artillery are to the east of the Royal Arsenal: they generally contain complete outfits for 10,000 men, including the muskets, pistol, shot, shot-shells, whips, &c. From the upper part the storehouses may be seen in the field below about 1500 pieces of ordnance arranged according to their sizes. The Royal Artillery Barracks are on the north side of Woolstoum Common. The length of six ranges, is 1200 feet long, with an elegant entrance tower in the centre. A spacious chapel in the east end has accommodation for 1000 persons. The other parts of the building consist of the library and reading-rooms, and a splendid suite of apartments, in which balls and other entertainments are given. The interior is divided into two quadrangles, with stables and barracks for the horse-artillery and a large riding-school. The whole establishment can accommodate from 8000 to 4000 men.

The Royal Military Academy is on the west side of Woolstoum Common, towards which it presents a broad front; the central tower, with its four domed turrets, is a picturesque object in the distance. The Academy was established as early as 1719, but the present building does not entirely date from that period. It was built for young men under instruction in whatever is requisite to qualify them for artillery officers and engineers. The Master-General of the Ordnance for the time being is the governor. The resident officers are, a lieutenant-governor and inspector, a professor of fortification, masters of drawing, languages, &c.

The Rotunda, south of the town, on the west side of Woolstoum Common, is a depository for models connected with military and naval architecture, spectra of maps, arms, military machines, and a variety of other things connected with military and naval affairs. The building is o
a tent-like form, with 24 sides, the diameter being 120 feet. It was originally erected in Carlton House Gardens, by George IV. when prince regent, for the reception of the allied sovereigns when they visited England in 1814, and was afterwards presented to him by the garrison at Woolwich. The centre of the cone which forms the top of the building is supported by a pillar, round which are arranged specimens of old English weapons, such as matchlocks, wheel-locks, bills, partizans, old swords, &c. In the centre of the upper room are an altar-screen, models of fortified places, Indian arms, and a variety of other military and naval curiosities.

The Roydard is at the east end of the town, in which one of the largest size is made.

Besides the places already described there are the Royal Marine Barracks, the Barracks of the Royal Sappers and Miners, and the Royal Ordnance Hospital.

(\textit{Penny Magazine}, Nos. 92, 442, 445, 447; \textit{Population Returns in good repair}.)

\textbf{WOOTTON-BASSET. [Wiltshire.]}

\textbf{WORCESTER}, a city and capital of the English county of the same name, is situated on the river Severn, upwards of 100 miles in a direct line west-north-west of London, 112 miles by the road. The boundary of the city was originally determined by a wall which commenced near Edgar's Tower, at the Castle gate, passed at the back of St. Peter's to a gate which was called Sid- bury Gate, and thence to Friars' Gate, which stood near the south-east corner of the town, and descending the northeast present corn-market, round the hop-market, to a bridge built in 1313, and fortified with a strong tower, which stood near it. It then followed the course of the river to the Priory gate, and thence to the Castle gate, and so to the west end of the city. There were four gates (besides the tower on the bridge) the last was taken down in 1797. The present limits of the city of Worcester extend from north to south about three miles, and nearly two miles from east to west.

\textbf{In the early part of the} 17th century, the city was the residence of the bishop of Worcester, and included the parishes of St. John, St. Michael, and the extra-parochial district of the College precincts, St. Peter's (in part), and the tithe of Whittington attached to the parish of Claines. The first nine parishes composed the city previous to the Boundary Act, and were united for the maintenance of the poor by an act of 1833.

\textbf{Boundary Act:} nearly the whole are built over, and there is no great extent of rural district within the increased limits.

Worcester is built almost entirely of red brick, with the exception of some public buildings, the churches, and the walls of the city, which are about of limestone. The wind is light and cheerful; their appearance is clean and neat; the houses various and well provided; and, like the dwelling-houses in London, the houses are, in general, of one story and half. The chief thoroughfares are Broad Street, Broad Street, Sidbury, College Street, the Cross, Foregate Street, and the Tithing. Besides the cathedral, there are twelve churches—St. Nicholas, St. Martin's, St. Swithin's, All Saints, St. Andrew's, St. Alban's, St. Michael's, St. Helen's, St. Peter's, St. Clement's, and St. John's. St. John's is the parish church of what may properly be termed a suburb of Worcester, and is on the opposite bank of the Severn to the main portion of the city. There is a Roman Catholic chapel, and places of worship for Jews, and for Unitarians and Dissenters. In 1847, the Jews were numerically in excess of the Protestants; the Dissenters were next in number, and the Catholics last. The population of the city, in 1841, was 42,564, and in 1851, 42,729, of whom the males were 21,325, and the females 21,404.

\textbf{A cathedral existed here in the time of the Saxons; but it was destroyed by fire, and was superseded by a new cathedral, built by Oswald, the bishop, in 1006. This church, dedicated to St. Peter, stood on a fresh site, and was consecrated in 1094. This cathedral likewise twice suffered from fire. After the second conflagration, for sixteen years it remained in a dilapidated state. Repairs, so great as to necessitate a new building, were undertaken in 1244, and in January, 1248, the church was re-opened in the presence of the king. Various alterations and additions were made in 1224, and again in 1380.}

Worcester cathedral is built in the form of a double cross, with double transepts. The tower, which is 193 feet high, rises from the intersection of the western transept with the nave and choir. The nave, which appears to be the oldest part of the present building, is divided from the aisles by ten clustered columns on each side, surmounted by pointed arches. The roof is groined, and ornamented with flowers, heads, and other forms of decoration. The height of the nave is 67 feet, the length 174 feet, and the width 30 feet. The choir has also a handsome groined roof; the altar is of stone, both richly sculptured. The tomb of King John is in the centre of the choir. There is a Lady-Chapel, which corresponds in date and style with the choir. The total length of the cathedral is 422 feet; the greatest width is 149 feet. The present tower, 72 feet from the ground to the top, is 120 feet. The exterior is plain, but a fine effect is produced by the apparent lightness of the architecture, and by the pinnacles, which rise not only from the tower, but from almost every termination of the building. The clusters form a quadrangle on the south side; the east end is the chapter-house, which contains the cathedral library. The cathedral is in an indifferent state as to repair, and costs a considerable sum yearly for that purpose. Many of the restorations which have been made in former times in various parts of the interior, are in the most incongruous and unsuitable styles.

The corporation of Worcester consists of a dean and ten prebendaries or canons. There are also seven domestic canons and a minor canons. There are ten chaplains, and two or three other officers. The total yearly income, on an average of three years ending in 1831, was 21,088l.; the annual expenditure, by the same average, was 3009l.

The other principal buildings are, the county courts, later erected, a great room, the present city hall, the High Tower, and the guildhall. In the guildhall is a large room, which is used for public entertainments. The present bridge over the Severn was built in 1780.

The living in the city of Worcester, estimated on an average of three years ending 1831, were—St. Albans's, rectory, in the gift of the bishop of Worcester, with a net yearly income of 744l.; All Saints, rectory, in the gift of the crown, with a net yearly income of 183l.; St. Andrew's, rectory, in the gift of the dean and chapter of Worcester, with a net yearly income of 165l.; St. Clement's, rectory, in the gift of the dean and chapter of Worcester, with a net yearly income of 101l.; St. Helen's, rectory, in the gift of the bishop of Worcester, with a net yearly income of 136l.; St. Martin's, rectory, in the gift of the dean and chapter of Worcester, with a net yearly income of 376l.; St. Nicholas, rectory, in the gift of the bishop of Worcester, with a net yearly income of 206l.; St. Swithin's, rectory, in the gift of the dean and chapter of Worcester, with a net yearly income of 233l.; and St. Swithin's, rectory, in the gift of the dean and chapter of Worcester, with a net yearly income of 170l.

According to the Education Returns (1833), Worcester contained eight infant-schools, with 501 children; thirty-nine daily schools, with 1130 males and females; six national schools, with 657 males and females; one daily free grammar-school, founded by Queen Elizabeth, with 23 males; nine-day and boarding-schools, with 230 males and females; one boarding-school, with 59 males; and twelve Sunday-schools, with 1687 males and females.

A manufacture of cloth was once carried on here to a considerable extent, but was in the course of time abandoned. The principal trade is now that of the clothing of sheep, and the number of the people inhabitants; but this manufacture also declined, and is gradually diminishing. China is made here: there are three different factories of some celebrity. The principal inns are the Star and Garter, the Unicorn, and the Crown.

Worcester, previous to the Municipal Reform Act, in 1835, was a corporation consisting of a mayor and six aldermen, 24 capital councillors (of whom the aldermen were part); 48 capital citizens, and an indefinite number of minor citizens; the last-mentioned were entitled to vote for the two members elected for Worcestershire to the House of Commons. The titles to admission to the freedom were birth, apprenticeship, and gift by the council. The number of freemen, in 1835, was 2900, and the population of the borough was 18,500; the population of the actual town and suburbs at
the same time (1835) was 27,000. The governing charter was 19 James I. The borough is now divided into five wards, with 12 aldermen and 36 councillors. The number of burgesses on the roll at the first registration, in 1833, was 1022; the number on the roll in 1857 was 1406, besides whom there were 944 freemen who were parliamentary electors, though not burgesses.

Worcester, previous to the Reform Act, returned two members to Parliament. The right of voting was in the citizens; the largest number of electors who had polled at any election during thirty years preceding 1831, was 2179 in 1807. Under the Reform Act, Worcestershire still returns two members to Parliament. The number of electors on the register in 1835-6 was 2579; in 1839-40 the number was 2561, of whom 1034 were 10l. householders, 947 were freemen, and 580 were entitled to vote for more than one qualification.

The limits of the city of Worcester and the parliamentary borough are co-extensive. The population of the city, as given in the Population Returns for 1841, was 26,306, of which 11,614 were males and 14,692 females. The population, as returned for the parliamentary borough, was 26,306, which is said to be a more correct return of the actual population than the above, as given for the city.

History.—Lambard, an antiquary contemporary with Camden, remarks, in his 'Alphabetical Description of England,' that he never met with a place that had so great experience in the calamities of the intestine broils of the kingdom and other casual disasters as the city of Worces-
ter. The city was destroyed by the Danes and rebuilt about 894 A.D. by Ethelred. In 1041 the town was plundered and partly burnt by the troops of Hardicanute, which were sent to force the reluctant inhabitants to pay a tax which the king had imposed. In 1074 a body of troops under the conduct of the Duke of Normandy assembled here to quell a conspiracy against William the Conqueror, and to guard the passes of the Severn against the rebels. In 1088 Berwald Neumark unsuccessfuiuly besieged the city. In 1113 the town was beleaguered, and the cathedral, was consumed by fire. In 1133 a great part of the city was again burnt by a casual fire, and the cathedral damaged. In 1159 the forces of the Empress Maud attacked the city, forced an entrance on the north side, and fired and plundered it. In 1149 King Stephen burnt the city, but the castle, which had been strongly fortified, resisted his attempts. The remains of one of the forts then razed may be seen on Red Hill near Digley: another stood on Hawley Hill, from which the castle was commanded. Eustace, his son, vigorously besieged the castle, but was as vigorously repulsed; in revenge he fired the town. In 1157 Worcester was fortified against Henry II. by Hugh Mortimer, but afterwards submitted. In 1216 again.selected to its garrison, and in 1216 the king's troops, with the earl of Chester, plundered the city, which had revolted. King John was buried here in this year. In 1225 a great tournament was held here. Bishop Blosiex communicated all persons concerned in it.

In 1263 Robert Ferrars, earl of Derby, Peter de Montfort, earl of Leicester, and other barons of their confederacy, besieged and took Worcester. The church was spared, but the houses rifled. In 1264 King Henry III. was in the city. In 1266 Sir Simon de Worcester by a seal, whose hands he had fallen at the battle of Lewes. In 1342 and 1349 the inhabitants were afflicted with the plague. In 1401 Worcester was burnt and plundered by Owen Glendower with their Prince. Henry IV. drove back into Wales. In 1494 there was an unusual and destructive flood of the Severn. In 1495 executions took place here, and 500 marks were paid as a ransom for the city, which was seized by Henry VII. In 1534 the city was given to Sir William Paget, and in the following year it was scourged by the sweating sickness; in 1537 there was again a pestilence. In 1542 Worcester was besieged by the parliamentary forces. Lord Coventry and Sir William Russell commanded the garrison, and were reinforced by a strong body of horse under Prince Rupert and Prince Maurice. Colonel Fiennes commanded the attack, overcame an obstinate resistance, and took possession of the town. The royalists retreated towards Herefordshire. Various es-
cesses were committed by the insurgents; the cit-
ty was plundered, and the inhabitants were required to raise a loan of 3000l. for the use of the parliament. Defeat neither changed the opinions nor weakened the re-
solution of the citizens. In 1643 they again raised money for the king's cause, the walls were repaired, fresh men were mounted, and other evidence given of renewed res-
istance to the parliament. Another siege was sustained in 1646, which, after many sallies and many skirmishes, was concluded by a treaty. A third and most important battle was fought here by the same contending parties in 1651. In the month of August Charles II. disposed the small adverse garrison, which were in possession of the town, and occupied it and a district to the west of the city. Seven-Sisters, the nearest town to the north, was taken by Cromwell, who encamped on Red Hill, about a mile north of the city. While the assault was conducted with vigour and ability, the defence on the part of the Royalist displayed neither courage nor judgment: it is asserted by contemporaries that Charles led his cavalry in person, but it would appear otherwise from Lord Clarendon's account. The result was a total defeat of the royalists and the rapid flight of the king, which was effected with great difficulty.

The site of the castle which from time to time has been so many sieges and so frequently changed governors is on the south side of the cathedral. There is no architectural remains whatever. A small part of an old ecclesiastical house, the nunnery of Whilamut, is called the Judges' Hall, and bears the marks of the late destruction. It was built from the remains of a house which takes its name from a house of Franciscans which formerly existed here, and the remains of whose building were demolished in 1823. The Dominicans, Penitents, Sack Friars, and Friars of the Holy Trinity had likewise their establishments here.

(Nash's Worcestershire; Green's Antiquities of Wor-
cester; Report on Municipal Corporations; Boundary Reports, &c.)

WORCESTER COLLEGE, Oxford. This college, originally Gloucester Hall, was founded in 1714, pursuant to the will of Sir Thomas Cooke, of Bentley Peascot in Worcestershire, Bart., for a provost, six fellows, and as scholars, the scholars to be elected from the school of Stonegrove, Fossebridge, Wooton, Bath, and a keeper, or in default of persons properly qualified to teach these schools, from any other endowed school in the county of Worcester. The schools have a priority of claim in the order in which they stand. A preference is to be given in all instances to the scholars of the Whitby Grammar School who are qualified to offer himself as a candidate who has not been at one of the aforesaid schools for at least two years previous to the election. Two of the fellows on this foundation may laymen, provided they do not reside in the county of Worcester. The number of the three senior fellows of the foundation are the election. The college has since received considerable endowments:

James Finney, D.D., prebendary of Durham, left by his will, in 1727, provision for two fellowships and two scholar-
ships for natives of Staffordshire.

George Clarke, D.C.L., Fellow of All Souls College, and one of the representatives in parliament for the Universities, left by his will, in 1734, estates for the endowment of three fellowships, and three scholars to be elected 'out of such persons as are born of English parents, in the provinces of Canterbury and York, and none other. A preference is given, ceteris paribus, to the sons of clergy and the children of the Church of England's auxiliary clergy.' who is always one of the fellows of this foundation may not go into orders, if the provost and four of the six senior fellows shall think fit to dispense with them. The provost and six senior fellows (who may be present in their places) with Thomas Cookes and Dr. George Caxton are the electors.

Sarah Eaton, daughter of Byron Eaton, D.D., formerly principal of Gloucester Hall, left by her will, in 1731, estates for the foundation of seven fellowships and five scholas-
tships. Candidates for scholarships on this foundation must produce certificates signed by the bishop of their respective dioceses, by the ministers of their parishes, and by two or more respectable inhabitants of the same, bat
they are sons of clergymen of the Church of England, and want assistance to support them in the University; the present subscriber is one of the founders of Sir Thomas Cookes and Mrs. Sarah Eaton are the electors.

The fellows of the college are, in all instances, elected out of the scholars of their respective foundations, and must all have taken the first degree, which is not those dispensed with by the statutes before mentioned.

There are likewise two exhibitions left by Lady Holford, in aid of exhibitions from the Charterhouse, and one by Mr. Kay for a native of Yorkshire.

The foundations are of the value of 200 a year, the proceeds of which follow the foundation of Sir Thomas Cookes and Mrs. Sarah Eaton.

Sir Thomas White's intermediate establishment acquired a considerable degree of reputation, though with some important exceptions that of his scholar's, who was no more known as a maker of scholars than as a maker of teachers.

Sir Thomas White's intermediate establishment acquired a considerable degree of reputation, though with some important exceptions that of his scholar's, who was no more known as a maker of scholars than as a maker of teachers.

Among the eminent men connected with Sir Thomas White's foundation who received their education in Gloucester Hall, were Thomas Coryate the eccentric traveller, Sir Kenelm Digby, Thomas Allen the mathematician, and Evelyn the poet.

The river Stour has a more striking contrast than the old and new buildings of Worcester College as seen from the inner court.

The present chapel occupies the site of that which belonged to Gloucester College, erected in the fifteenth century, and which was made use of to the last, but was pulled down in Edward VI.'s time by Sir John Williams, Knight, afterwards Lord Williams of Thame. The modern edifice, extremely plain as a structure, forms part of the general design first suggested by Dr. Clarke for rebuilding the hall and library, in 1720. The re-construction of the college however proceeded slowly.

The range of new buildings on the north side of the inner court, containing the provost's lodgings, and the apartments of the fellows and scholars, were not completed till 1776. The present hall, forming the south side of the entrance-court, corresponding with the chapel opposite, was not finished till 1784. The south side of the inner court is still occupied by the old buildings which belonged to Gloucester College.

WORCESTERSHIRE, an inland county of England, is bounded on the north by Staffordshire and Shropshire, on the east by Warwickshire, on the south by Gloucestershire, and on the west by Herefordshire. There are several detached portions of this county: the most important contains the town of Dudley, and is surrounded by the county of Staffforshire. Another detached part, forming a small-earther direction from the main body of the county, contains the market-town of Shipston-on-Stour. There extends in this direction a narrow promontory of Worcestershire, containing the towns of Broadway and Ebley. The greatest length of the county is about 20 miles, in a direction from north-east to south-west; its greatest breadth is about 22 miles, in a line running east to west. Worecestershire, the county town, is distant from London by the nearest turnpike-road 112 miles. The principal towns are Tewkesbury and Leamington. The area of Worcestershire is 718 square miles, or 459,710 acres. The gross population in 1831, amounted to 211,365, being an average of about 272 persons to a square mile. On comparing this amount with the average in the rest of the country, we find, with two exceptions, the population of Worcestershire to be the most dense. The population of Gloucestershire, according to the returns of that year, was about 307 to a square mile; of Herefordshire, 122; of Shropshire, 163; of Staffordshire, 121; and of Worcestershire, 233,336. In respect of size it is the thirty-fifth of the English counties. In amount of population (1841) it is the twenty-fifth.

Surface.—Worcestershire is generally a flat country, on either side of which are two nearly parallel ranges of hills, which partly bound and partly intersect it: the intermediate space is for the most part a fertile plain.

The eastern range of hills commences in the north in the Clent Hills (a portion of which are in Worcestershire and a portion in Staffordshire), and the western range commences in the neighbourhood of Bewdley, and runs southward through Abberley and Malvern to the great chain of Malvern Hills, in which it terminates. The principal hills not comprised in or bordering on these chains are Breton Hill, situated about three miles south of Pershore, Broadway Hill, near the town of that name, in the south-eastern extremity of the county, and the wide range of hills extending from Croome northwards towards Worcester.

The Severn.—The principal rivers are the Severn, the Avon, the Teme, and the Salwarpe.

The Severn, having in two places formed the boundary of Worcestershire with Shropshire, enters the latter county at Bewdley: the bearing of its course is for the most part southerly: passing the towns of Stourport, Worcester, and Upton, it becomes near Ripple the boundary of Gloucestershire and Worcestershire, which county it finally quits at Chaslely Rye. It is navigable for vessels of eighty tons as far as Worcester, and for barges of fifty to sixty tons above that city. Some attempts have been made to improve the navigation, but no result has yet been accomplished. This river is valuable for its salmon, and abounds with eels, lampreys, and lamprey.
dary of Worcestershire with Herefordshire. It falls into the Severn near Powick, about three miles south of Worcester; it is not navigable. The stream is good for fishing, and trout and greyling are abundant.

The Stour, a smaller river than those above mentioned, rises to the north of Bromsgrove, flows through Droitwich, and falls into the Severn near Claines.

Roads.—The principal roads are from Birmingham through Bromsgrove, Droitwich, Worcester, Severn Stoke, and Stourbridge to Kidderminster, and Gloucester; this line was formerly the main communication between Birmingham and Bristol, but the traffic upon it has very greatly diminished since the construction of a parallel line of railway from Birmingham to Gloucester. Another important road from Dudley, Stourbridge, Kidderminster, to Stourport; or, leaving Stourport on the left, through Haltcliff and Upperosley to Worcester. From Worcester to Malvern there is considerable traffic on a road communicating with Ledbury and Hereford. There are likewise good turnpike roads which connect the county-town with Tenbury and Bromyard: mail-coaches which formerly travelled along them to Ludlow and Leominster were discontinued in 1842. At the same time a mail from London through Oxford, Broadway, Bengworth (a suburb of Evesham), Pershore to Worcester, was taken off the road and the letters forwarded by railway. Worcester is distant from Birmingham by road 26 miles, from Cheltenham 26, from Oxford 88, from London 112, from Bromsgrove 13, from Stourport 10, from Bromford, Ledbury, and Tewkesbury 11 miles.

Railways.—The chief railway in this county intersects it diagonally from north-east to south-west, and communicates on the one side with Birmingham, on the other with Tewkesbury, Cheltenham, Gloucester, and Bristol. The main line parallels the turnpike-road leading from Tewkesbury to Worcester and Birmingham, on the south-east. The part of the line nearest to Worcester is about three miles distant, at Spetchley, where there is a station.

A portion of the London and Birmingham Railway likewise traverses the parish of Yardley, the north-eastern extremity of the county. There are tram-roads, on which horses are worked, in the coal-districts, but none of them are long or of great importance; only a small portion of the electoral个人观点 is from Stratford-upon-Avon to Moreton pannes through Worcestershire.

Canals.—The northern part of the county is intersected by several canals, which are of great commercial importance. The chief canal reaches from Birmingham to Worcester, and passes through the district of Droitwich, and having two branches, one to Dudley by way of Halesowen, and the other from King's Norton to Stratford-upon-Avon. From Dudley there is a canal to Stourbridge, Kidderminster, and Stourport, at which last place it joins the Severn; it was formerly a railway, and this canal to Leominster and Kidderminster in Herefordshire, but only a portion of the work, from Woorfordon to Tenbury, and thence to the neighbourhood of Mamble, has been executed: funds are wanting for the undertaking, and it is not likely that it will ever be started.

Geology.—The geology of Worcestershire has been fully detailed by Mr. Murchison, in his valuable work on the 'Silurian System.' The county is composed for the most part of new red-sandstone, lias, and oolite; other formations are visible in the shales of the Malvern Hills, in the districts bordering on Tenbury, Bewdley, and Dudley, and in the Lickory and neighbouring hills in the northern part of the county. The new red-sandstone comprehends the formation which is watered by the Severn, together with the north-eastern portion of the county: its lower bed being found round Witton, Stourport, Kidderminster, Bromsgrove, and Alvechurch; and the higher, called the Kepper beds, round Droitwich, Worcester, and Upton. The lias formation is thin almost throughout the county, and Evesham, in the vale, is covered by the Avon; it extends from Foster Green to the limits of the county near Tewkesbury. The portion of the Malvern Hills within the boundary of Worcestershire consists of trap; while the Silurian rocks, the Cambod sandstone, Ludlow rock, and Wenlock limestone appear in the northern portion of the chain. The lower coal and ironstone beds are found at its termination, to the north of Abberley Hill, in the Forest of Wyre. Here also is found the old red-sandstone formation upon which Tenbury stands, and which is the prevailing stratum throughout the adjoining county of Hereford. Bewdley is situated near the junction of the lower red-sandstone with the coalfield of the Forest of Wyre. The town of Dudley stands on the thicker coal-measures, Wenlock limestone appearing on its north-west, and the coal in the south-east. In the Lick ley there are several altered sandstone beds, the lower coal-beds, and trap; the latter rock forming the range connecting with the Clent Hills of Staffordshire. In the neighbourhood of Droitwich and Stickle, or, are saliferous beds, and a large quantity of salt is manufactured. A full and interesting account of them is given in a pamphlet by Dr. Hastings. They are likewise described by Mr. Murchison in his 'Silurian System' (p. 31), to which work we refer our readers for further particulars of the coal-field, and remarkable geological phenomena of the county.

In a paper by Mr. Leonard Hornor, in the 'Geological Transactions,' there is a full and interesting account of the geology of the Malvern Hills.

Agriculture.—The climate of Worcestershire, specially in the middle, south, and west of the county, is remarkably mild and healthy; and the fruits of the earth are brought to early maturity. The vales of Severn and Avon are but little raised above the level of the sea; and it has been observed, that an elevation of sixty yards makes a difference in climate equal to a degree of latitude towards the north, soil and other circumstances remaining the same. The higher parts of the county, between Bromford and Tewkesbury, are high enough to form a break in the line of the rain, and the higher hills, such as the Malvern Hills, are proportionally colder and later. They tend to shelter the sun between them from the cold winds, and add to the mildness of the climate there.

The Teme winds through the county for about 30 miles. Along its banks are many hop-gardens and orchards; proof of a good deep soil, and the lower parts form pastures and meadows. Several lesser streams run in their own valleys, their soil being generally poor, except in a few instances in which bogs have been formed by the stagnation of the waters, with their accompanying peat. Except where the higher hills rise in praiseworthy surface is in general gently undulating. One-half of the county is park and meadow land. The soil which are met with near Kidderminster are some of the most productive, and others very poor, as about Mitten and at Worlester. The mixed springy gravels and gravelly loams to the north of Bromsgrove are less fertile than the higher and more level country. Upon the whole, few counties in England contain so much good land as a consequence, fewer wastes. Viewed from the hills, the valleys give the idea of very successful cultivation. The soil of this county may be arranged, without pretensions to great accuracy, as follows:—

<table>
<thead>
<tr>
<th>Soil Type</th>
<th>Acres</th>
</tr>
</thead>
<tbody>
<tr>
<td>Light land, sand, sandy loam, gravel, and gravelly loam</td>
<td>120,000</td>
</tr>
<tr>
<td>Mixed stiable loams adapted to general culture, fit for turnips, hops, fruit, &amp;c.</td>
<td>120,000</td>
</tr>
<tr>
<td>Strong clay loams, which, where they are dry, are adapted to hops, fruit, wheat, and beans, but too strong for turnips</td>
<td>120,000</td>
</tr>
<tr>
<td>Natural meadows along the caravan of the rivers</td>
<td>50,000</td>
</tr>
<tr>
<td>Upland pastures, parks, and plantations</td>
<td>50,000</td>

500,000

The farm-houses in Worcestershire are generally substantially built, but they are often inconveniently situated with respect to the land, owing to their old and common fields, and the annual are neither in fine or of the end. Some modern erections are an exception; but, in general, the offices and buildings for the convenience of the farmer are not of the best construction. The farms are most of them small, which indicates ancient cultivation; but they are gradually enlarging.
uniting several of them under one tenant. Leases are not generally granted by the proprietors, or demanded by the tenants, except where improvements are intended, in which case they are usually for 21 years. Those who grant new leases, when it has been thought fit, or out of a desire to have only tenants at will, are apt to load them with conditions, which at best are useless, and only impede improvements. All that is required is some security against over-cropping at the end of the lease, and against wilful damage done to the land. This end may be secured by requiring the lessee to engage to pay damages on deterioration of the land; preventing the sale of hay and straw, except on condition of purchasing a proportional quantity of dung, bones, lime, &c., to be laid on the land, and all the dung done in the last 2 years; and also by giving the same security for the succeeding tenant, which will secure a proper quantity. The commutation of the tithe for a rent-charge greatly tends to encourage improvements, the whole profit of which is secured to the improver without participation. It is a very great relief to the farmers of the district.

The ploughs in common use in Worcestershire have two wheels attached to the beam, as in the Rutland plough. They are usually drawn by three horses, and easily managed in soils which are not stony. In the vale of Evesham, where the land is more level, there are ploughs with only one wheel, but the old heavy swing ploughs are much the best. The ploughs are generally of such a way gradually to lighter ploughs with one or two wheels. In the light sands a double plough making two furrows at once has been in use, but if it is drawn by four horses it is better to use single furrows, as it is only useful where one man can plough with two or at most three horses abreast, which is guided by reins. Thus a man and at least one horse is saved, and good work is done.

The other agricultural implements in use were formerly only carts, wagons, rollers, and harrows. All the new implements have been only lately recommended; and their general introduction goes on slowly, many disappointments having arisen, owing to a want of sufficient skill in the farmers; and it is only in the last year or two that large orders have been given for the most approved substitute.

The practice of following during two successive winters and sowing barley in the second spring, has been adopted by some farmers with great success, sheep having been folded on the land the last winter. The practice of following during two successive winters and sowing barley in the second spring, has been adopted by some farmers with great success, sheep having been folded on the land the last winter. The land is made very rich and manured by the straw; the hay saved is of the best quality; and the grass-seeds come up well after the following. Ons are not so general a crop, and no more are usually sown than will supply the wants of the farmer's horses. Beans are set or dibbled in by women, who use a long dibble. They are hoed three times, and, in general, the return is abundant, frequently 40 to 45 bushels per acre from 3 bushels set. The produce of beans is greater than the wants of the county require.

Vetches are a valuable crop in lands which are too heavy for turnips, either because they cannot be well tilled or to soil horses with in the stables. If they are sown at regular periods, so as to keep a constant succession of them from May to November, which may easily be done by sowing winter oats one or two months before the wheat season, and spring oats in April, all needful quantities as the stock may require. Thus not only is there a great saving in fodder—for the horses require no oats if they have good vetches with the pods and half-form ed seeds—but the cheap manure is made for the land. Vetches may be looked upon for heavy soils as turnips are for the lighter. They require less tillage and hoeing, and clean the land by smothering the weeds. The land should always be well manured for them to secure a heavy crop. It is not advisable to wait for a second growth of vetches; as soon as they are cut or fed off, the land should be ploughed; and if no intermediate crop is sown, it can be worked as a fallow for the next crop, which may be wheat, beans, or barley, according to circumstances.

Potatoes are raised in great abundance in this county, and supply the markets of Birmingham and Staffordshire. There are many varieties of early and late potatoes which have provincial names, but which it would be difficult to ascertain the productive merit of, as their names are not generally known. The potatoes used formerly to be sown broadcast, and some farmers still adhere to the practice; but all the best farmers, especially where the farms are large, adopt the system of sowing in drills.

The Kidderley sands have long been famous for the growth of carrots and for raising carrot-seed. The ground is trench-ploughed. The seed is mixed with sand to prevent its adhering by its edges, which have small hooked fibres all round. A drill is opened by a machine, and the seed is deposited by hand. A machine that will drill carrot
seed is still a desideratum. The time of sowing is in March. Great attention is paid to hoeing and weeding as soon as the plants appear; for the weeds are very apt to get the start of them. This makes the cultivation expensive, but the return is very great, without much exhausting the soil. They sell readily for two shillings per cwt. on the spot, and a crop of fifteen to twenty tons per acre is not uncommon, that is, from 30l. to 40l. per acre. A part is used for culinary purposes in the towns, and a part given away to the poor, who are very grateful to them, and they do well upon them. The orange-carrot of the large varieties is that usually sown. The Belgian white carrot is more productive, but not so saleable in towns. Flax is not cultivated as it should be in the richer soils: this is owing to the small landlords or farmers, who probably think the cultivation as exhausting the land: under proper regulations it might be a source of great profit both to the landlord and the tenant; and it may be laid down as a general rule, that what is profitable to the tenant will in the end be advantageous to the landlord, and that both may be consulted without many prohibitions or restrictions.

Profits occupy some extent, and are attended with great results, as well as, occasionally, with very great profits. Much may be made of them, but, as with all other crops, have been very advantageous to the hop-farmer. The cultivation of this plant is a perfect garden culture, chiefly by the spade. Much manure is required if used the land is not naturally very rich. Deep meadows and trenched up pastures and new and abuminous crops. Consists of rotten dung mixed with sods, and sometimes with woollen rags, are used by the best hop-growers. [Hops.] The average expense of the cultivation, exclusive of the diminution of the size of the tenant, in the county was about £600 acres in 1807. In a soil so well suited for orchards as in found in certain parts of Worcestershire, it is surprising that the cultivation of fruit-trees is so far behind other improvements. The county is very well planted with fruit-trees which are not vigorous, but show great symptoms of age and decay; some fresh plantations have been made, but even in these no great attention has been paid to have fruit of the best quality, especially apples for cider. The trees stand so nearly one another, and they are seldom sufficiently protected from injury by cattle turned out to feed on the herbage. Formerly fruit-trees were planted in hedgerows, which only enticed depredations, and did more harm by their shade on the land than they did good: now they have been made into small trees. The deep loams on a subsoil of soft sandstone are the most suitable for orchards. These are found in the western part of the county. The best loam inclines to a marl. The stooks are obtained from the eaves, where they are shaved off, and the scions inserted into the naturally-called grass-grafting or saddle-grafting. They begin to bear in about five years. In this case, the greatest attention is not always paid to the age of the tree from which the graft is taken; and thus many disappointments arise, as the young trees showing all the symptoms of the diseases of age. It is not recollected that the life of the graft is probably only a continuation of the life of the parent tree; and if this is old and exhausted, the graft will soon show the same defects and diseases. Most of the best old sorts, such as the golden pigeon and several others, stand too nearly together, and the early extant, and grafting can retart it. The only means of obtaining fine sorts is to sow the seeds, and let the wild tree show fruit: in many hundreds of wild apples one may be found that is good; and this may be perpetuated by grafting for a couple of centuries. Many of the sorts of horse and judicious care will greatly increase the produce. The common method of making cider is by crushing the apples by means of a heavy stone rolling in a stone trough, and moved round by manual labour or by a horse. Pear-orchards are common in Worcestershire.

There is much fine timber growing in the hedgerows, whether advantageously to the proprietor or farmer may be matter of doubt: elms predominate, and grow to a large size where they have room. There are also some woods and plantations of oaks and ash, the underwood of which forms valuable coppices. In many of the parks and pleasure-gounds which surround the seats of the nobility and gentry are many splendid trees preserved for ornament, and the whole country, when viewed from an eminence, gives the idea of a thickly timbered country, and of great richness.

Draining has been practised for a long period on many of the principal estates, chiefly on Ellington's system, which is excellent for carrying off deep-seated springs, but not for those who are very distant from them, and it is not well understood. Many of the low grounds on retentive subsoils would be much benefited by this operation, and nowhere would it repel the outlay better. Paring and turning the surface of boggy land, where the grass is coarse and weak, and shallow, and the persons, who probably are not restricted by their landlords. The first crop potatoes, which always do well in the ashes; the next wheat or oats; and the land should then be laid down again with the best grass-seeds; a previous dressing with lime is much improve the subsequent pasture.

There are not so many irrigated meadows as you would expect along the banks of so many rivers and water streams: this is owing in part to the rights of certain landholders erected on every stream, which prevent the free use of the water at all times, as in other counties: when the water is dis-oblisbed, the water has been brought from a considerable distance by canals, which supply several farms on the estate. The water is let on and off under strict regulations, and the damage on the grass is unknown. There is no doubt that many more water-meadows might be formed, without interfering with the mills; and many of the latter are small and insignificant, and do more harm by obstructing the course of the water, than they do profit to the owners, who are generally also proprietors of the land around.

There is no peculiar breed of cattle in Worcestershire. They are chiefly obtained from Herefordshire and South Wales. The Holderness breed has been introduced, as it is very well adapted to the county; they are all mostly crossed without much judgment. The best and most profitable breeds to stock in rich pastures are the Herefords and Devons, which get an excellent condition by a summer's run, and are then fed in the stalls with hay, turnips, and oil-cake in the winter; very fat beasts are sent up to Smithfield and to Birmingham every year from this county.

The sheep are mostly of the Leicester breed, with the suit the rich pastures. On the Malvern Hills are seen many small sheep, which have been mutton. The Cotswold, and a cross between them and the Ryeland sheep, are approved of by some: they have good carenesses, and bear large fleeces.

The swine are fat for farthing. There are no pigs of the most of the strong black breed. Oxen are seldom used on a farm. A little cross pure blood would greatly improve the pace and courage of farm horses. They would be lighter and more active, and thus do more work.

As is generally the case in the rich loamy soil, so as are found in the vale of Evesham, the roads were formerly very badly maintained. In 1792 a club of gentlemen and farmers was established for the especial purposes of attending to the roads, and regular scales and regulation were drawn up. Some of the members being appointed overseers of the roads, and availing themselves of the power of the highway act, without any oppressive demand or statute, duty, or additional highway rates, but simply by purchasing the materials, and placing men on the roads so that, that, from being nearly impassable, they soon became excellent; and the most determined grumblers and opponents of all improvement were forced to admit the great advantage of good communications, and the cost of them.

The following fairs are held in Worcestershire—Ashchurch, April 22, August 10; Bellbroughton, first Monday in April, Monday before St. Luke's; Bewdley, April 12, December 10, for hogs, December 11, cattle, &c.; Bromsgrove, June 24, October 1; Droitwich, Good Friday, October 23, December 21; Dudley, May 8, August 5, October 5; Evesham, February 2, Monday after Easter; Kidderminster, Holy Thursday, and three weeks.
after September 4; King's Norton, April 23, September 3;
Pershore, Faster Tuesday, June 28, Tuesday before All Saints, November 1; Kidderminster, Droitwich, Kidderminster, Kidderminster, Worcestershire, October
Shipston, June 22, Tuesday after October 10; Stourbridge,
(houses) March 29, September 8; Stourport, weekly, on
Wednesdays, from September to Christmas, for hops; Tenny
April, 23d, July 19, September 26; Upton, Midweek
Public-houses, in the town, and before
St. Matthew: Worcester, Saturday before Palm Sunday,
Saturday in Easter week, August 15, September 19.

The regular weekly markets are:—Bewdley, Saturday;
Bromsgrove, Tuesday; Droitwich, Friday; Dudley, Saturday
Salwarpe, Worcestershire, and Perswall, which include about 170 parishes.

Worcester, Bewdley, Bromsgrove, Dudley, Eyesham, and
Kidderminster, are described in separate articles.

The principal towns are the following:—

Droitwich, a parliamentary and municipal borough, is
situated on the small river Salwarpe, 116 miles north-west
from London, 66 miles north-east from Worcester. The
town is seated in a narrow valley, through which the river
flows, in an angle, to pass between the parishes of
Nicholas, and St. Peter, and parishes of Dodderhill, Marl-
borough, and Salwarpe. The total population of the
borough in 1841 was 5832, of whom 1346 were males, and
4856 were females. The number of houses was 1331
including the above three parishes; in the town the
population is upwards of 3000, a part of the town being
beyond the limits of the borough, the population of which
part in 1831 was 225. The population of the borough in
1851 was 2987. The Exchequer-House, where the duties
on salt are paid, is a fine ancient structure, with stained
Panoramic windows. There are two prisons. The living of St.
Andrew, with St. Mary Wilton, is a rectory, in the gift of the
crown, the average net annual income of which is £230.
The living of St. Peter is a vicarage, in the gift of Earl Stourton-Coleman.

Previous to the Municipal Corporations Act in 1835 the
borough of Droitwich consisted of two bailiffs and an
indefinite number of burgesses, the number of whom in
1835 was 50. The governing charter was 22 James 1. The
corporation contains a mayor, 12 aldermen, and 12 council-
noirs. The number of burgesses or municipal electors in
1837 was 228.

Previous to the Reform Act Droitwich returned two
members to parliament. The greatest number of electors
who had voted at an election previous to 1831 was 179.
It now returns one member to parliament. The number of
electors on the register in 1839 was 236, in 1839-40 the
number was 337, of whom 346 were adults, 3827.

The town, which is now extended con-
considerably beyond the limits of the municipal borough,
contained in 1841 a population of 6388.

The chief trade of Droitwich arises from its salt-springs,
from which salt has been made from time immemorial, but
the quantity has been much increased since about 1723,
by sinking the pits to a greater depth, where the brine
was found to be much saltier, and from which it rose as before
to the surface. The quantity of salt now made is not less
than 30,000 tons a year. The Worcester and Birmingham
Canals, which pass by Droitwich, and communicate with the
Severn.

The Romans made Droitwich one of their stations called
Saline. It is mentioned in Domessay-Book on account of the
tax derived from its salt-springs. The charter of 22 James 1,
which is given in existence; but a copy of a charter of King
John is given in Nash's 'History of Worcestershire,' vol. i.,
308.

Great Malvern, eight miles south-west from Worcester,
is a market-town, but contained in 1841 a population
of 2798, including 150 visitors. It is much resorted to by
neighbours, not only for its medicinal springs, St. Ann's Well
and Holy Well, but for the beauty and salubrity of the
situation. The wells are between Great Malvern and
Little Malvern, which latter is a small village about three
miles to the south. The Malvern Hills, which are in the
immediate neighbourhood, vary from one to two miles in
width, and rise in most parts with a very gentle ascent;
yet afford extensive and beautiful views into Wales and
the adjoining English counties. The situation is very
picturesque, and has six bells with chimes. The architecture of the
whole structure is very rich and light. When the monas-
tery was dissolved by Henry VIII, the inhabitants bought
the church and made it parochial. Of the rest of the mo-
astery nothing is extant, except a gateway, which is in
a good state of preservation. The monastery was originally
endowed by Edward the Confessor.

Pershore is a market-town, nine miles south-east from
Worcester, on the west bank of the Avon, which is here
navigable for boats. The town is well built and well-
paved. The inhabitants are chiefly employed in the
manufacture of stockings. The town consists of the parishes
of St. Andrew and Holy Cross, exclusive of their tow-
ships; the population in 1831 was 2536; in 1841 it was
3048. St. Andrew's is a small church with a square tower
containing six bells. The church of Holy Cross has a
lively square tower with eight bells, and there are some
ancient monuments in the interior. The living of St.
Andrew's is a vicarage, which consists of the curacies of
Holy Cross, Bford, Dofford, Brickfield, and Pinvin, in the gift of the dean and chapter of Westminster, and
of the average net yearly value of £700. There are
ruins of a Benedictine abbey.

Kidderminster-on-Stour, a market-town situated on the river
Stour, in an outlying portion of the county, in Warwick-
shire, about 27 miles east-south-east from Worcester, di-
rect distance. It was formerly a very large sheep-market,
and Sheepston has become Shipston. The town has no
large trade apart from the manufacture of stocking. The living is a rectory united
with the rectory of Tidmington, in the gift of the dean
and chapter of Worcester and Jesus College, Oxford, alter-
nately, of the average net yearly value £1000. The church is
dedicated to St. Edmund. The Baptists, Methodists,
and Quakers have chapels. The population of the town
was 2932; in 1841 it was 3464, including 102 persons in
the Shipston-on-Stour Union workhouse.

Stourport is a market-town, which derives its name
from its bridge over the Stour. The bridge is of stone, and
forms the boundary between Worcestershire and Staff-
shire, of which counties the river is here the
boundary. The town is rather irregularly built on a gentle
devotee, but the general appearance is handsome. The
five-roomed house is a picturesque old house, and there
is a small theatre. The church was built by subscription
in 1742. The living is a curacy in the parish of Old Swin-
ford, in the gift of the inhabitants, of the average
net yearly value of £140. There are places of worship belonging to the Independents, Baptists, Presbyterians, Quakers, and Roman Catholics.

There is a grammar-school, founded by Edward VI.,
and said to be richly endowed, but no return of the
number of scholars was given to the commissioners for inquir-
ing into the state of education in 1833; there were nine
other daily schools and two Sunday-schools. The popula-
tion in 1831 was 6148; in 1841 it was 7481, of whom
3654 were males, and 3827 were females. The manu-
factures consist chiefly of iron, glass, and fire-bricks. A
brickyard on the sand, 150 yards long by 300 feet wide, is
on the side of the glass, and is sold to a considerable amount for the same
purpose in other places. The bricks are made of the
Stourbridge clay, which has long been celebrated for its
excellence in resisting the action of fire. The production
is chiefly intended for the building trade. There is also a
most efficient navigable commerce by means of a branch from the Dudley
canal.

Stourport, 10 miles north of Worcester, is a handsome
and well-built market-town in the manor of Lower Mil-
ton, in the parish of Kidderminster and lower division of
Halfshire hundred. It has become a thriving place within
the last eighty years, before which period it was a small
and insignificant hamlet. Its prosperity is entirely owing
to local improvements by inland navigable canals. It is situated
near the confluence of the Stour and Severn; and the Staff-
ordshire and Worcester canals, which communicate with
Dudley, Stourbridge, and Kidderminster, enter the Severn
at Stourport. There is an extensive basin, opened in 1771, with wharfs and warehouses for the accommodation and as a general depot of the trade between the west and central portions of the kingdom. Stourport is a great mart for hops, corn, and apples. The market-day is Wednesday; and stone bridges and iron arches in the town are lined with carriages. The inhabitants of Stourport attend divine service at Milton; the living of which place is a perpetual curacy held with Kidderminster. The population of Milton chappel was 3012 in 1841. Stourport is a polling-place for the county.

Temesbury, formerly called Temebury, a parish and small market-town in the upper division of the hundred of Doddingtree, 17 miles north-west of Worcester. It is situated on the southern bank of the river Teme, which separates Worcestershire from Shropshire, and is here crossed by a stone bridge of six arches. The Kyre, a small but rapid stream, which falls into the Teme at the upper end of Tenbury, often occasions inundations in the town: this river is also crossed by a handsome bridge. The surrounding country is rich and fertile, and the grass-lands, yards, and orchards are very productive. Mineral-springs have been discovered in the neighbourhood. The Leominster Canal passes near the town, and supplies it with cheap coal from the Clee Hills: this canal was intended to have been carried to Leominster. The town of Stourport, but the original design has never been completed. There is a considerable trade in hops, cider, and perry; and the making of malt is carried on to some extent. The town consists chiefly of three streets, with an ancient corn-market, and a handsome bridge. The modern erection of the bridge was carried away by a flood in 1770, and the present edifice was erected in 1777. The living is a vicarage. The market-day is Tuesday, and there are fairs in April, May, June, July, and September, for horned cattle, horses, and sheep. The parish contains 4,510 acres, and in 1841 contained 1,849 inhabitants, namely, Tenbury parish, 1177; Berrington hamlet, 207; Sutton hamlet, 186; and the hamlet of Tenbury Foreign (252), with Kyrewood (27). Tenbury is a polling-place for the county.

Upton, a neatly built and thriving market-town, in the lower division of the hundred of Pershore, 8½ miles south of Worcester. It is situated on the bank of the Severn, in a flat and fertile plain. The river is here navigable for vessels of 100 tons burthen; and there is a basin for loading and unloading; and a considerable trade is carried on. A market-house, including under the same roof an assembly-room and a court-room for the use of the magistrates, has recently been erected. The course of six arches and the old church were injured during the civil wars, and in 1756 the latter was taken down and the present edifice erected. The living is a rectory, in the gift of the bishop of Worcester, valued at 1972 per annum. There are two day and Sunday national schools, one for boys and one for girls, the former supported by subscriptions and the latter by an endowment. The population of the parish was 2806 in 1841. Upton is one of the polling-places for the county.

Worcestershire is in the Province of Canterbury, and for the diocese of Worcester; 15 parishes and 8 chapels are in the diocese of Hereford. The diocese is divided into 10 deaneries.

The principal benefices are—

Net Value. | Poem.
---|---
Ripple | £1,116 | Bishop of Worcester.
Shipston-on-Stour | 700 | Dean and Chapter of Worcester.
Stoke Severn | 746 | Lord Coventry.

The yearly revenue of the bishop of Worcester, as an average of three years ending in 1820, was £695; for expenditure, by the same average, was £371, leaving at yearly income of 5890.

This county is in the Oxford circuit: a change in lately (1843) taken place in the order in which the town of Worcester is contended for by the assizes at Worcester, and that for the assizes at Oxford and before those of Staffordshire: the judges consequently go from Oxford to Worcester and thence to Gloucester. Worcestershire is the last town in the circuit, and the principal villages are Broadway, Bredon, Little Malvern, Blockley, Eckington, Redditch, Stourbridge, Alvechurch, Kidderminster, Monmouth, and Feckenham. Thirteen unions have been formed by the Poor Law Guardians for the accommodation of several of the parishes of Worcestershire, meet at Bromsgrove, Droitwich, Dibden, Evesham, Kidderminster, King's Norton, Malvern, Porchester, Shipston, Stourbridge, Tenbury, Upton, and Worcester.

The principal gentlemen's seats are—Cromes, belonging to Lord Coventry; Hagley Park, the residence of Lord Coventry; Witley, the property of Lord Ward, and belonging to the Earl of Shrewsbury (1843); the residence of the Queen Dowager; Hereford, belonging to the Hon. Robert Clive; Highfield, the residence of Lord King, the Earl of Oxford, belonging to Lord Osmersby; Windermere Park, belonging to Lord Sandys; Westwood Park, belonging to Lord Sandys; Kidderminster, belonging to Lord Sandys; Worcestershire, belonging to Lord Sandys; and Witley, belonging to the Earl of Shrewsbury.

Manufactures and Commerce.—Iron is largely manufactured at Dudley, in the neighbourhood of which there are likewise extensive coal-mines. In the northern part of the county a very large quantity of nails are made at there are likewise factories for fish-hooks and needles, and petros; there are also many glass works. The glass is manufactured at Stourbridge; a dressing-glove-trade is carried on at Worcester, and porcelain-manufactured to a considerable extent. The population of the southern and eastern part of the county is chiefly occupied with agriculture.

History.—The etymology of 'Worcester' is without plausibility adduced from 'Wyre-Cestre,' the Camp Castle of Wyre, under which name a considerable fort still exists in the neighborhood of Bewdley. The antiquities of the county little are little known; but there is however many evidences of its occupation by the Romans. During the Heptarchy, Worcester was the principal religious seat in England, and the inhabitants of the district were under ecclesiastical government. After the Conquest of the country, a government was changed. King of Worcester was changed, and the civil power confined to them. Of these first was Urso d'Abitot, one of William the Conqueror's lieutenants and favourites. This earl had many successors; and it retained or lost the name when it was mentioned by the county. The influence of the party which they had adopted in the government. During the war between Stephen and the Empress Matilda, and subsequently during the resistance of the barons to King John, the possessions of the earl of Worcester were frequently change by and by. The re-establishment of the Church of Worcester, to which the earl was very partial, laid hold of that opportunity of enlarging his possessions, by which they so much diminished the accommodations of the castle, as to render it no longer fit for the habitation of the sheriff's court, as it began to fall into decay. The greater part of the land was at that time in the hands either of the church or a few barons. Of the latter property great fortune took place after Perkin Warbeck's rebellion, and the earl was deprived of his French dukedom in consequence of the participation of several gentlemen in the county in the Powder Plot. Some of the conspirators in that plot retreated and were apprehended at Henslip, an old house, of which the most considerable edifice is situated between Droitwich and Worcester. During the Parliament the Worcestershire was on several occasions overrun by the contending parties. [Worcester.]

Antiquities.—The antiquities of this county are not...
markable. Three Roman roads have been traced: Ick- 
field Street, which ran from Alcester northwards to Staf- 
fordshire; a second road, which passed from Tewkesbury 
to Uley, Worcs., and so to Shropshire; and the 
ridgeway, which is the boundary of the county for a 
distance on its eastern frontier. Antient encampments 
may be traced at Malvern, at Bredon, and on the hills 
at Woodbury and Witney. There are many remains of 
early churches and of the ancient enclosures of 
Worcester, and the abbeys of Malvern, Bordesley, and 
Evesham. The most remarkable churches are the ca-
thedral at Worcester, the churches at Evesham, Malvern, 
Droitwich, Eastham, Naunton Beauchamp, Stockton, 
and Church Leach. (Nathan’s Worcestershire: Green’s An-
tiquities of Worcester; Corporation and Boundary Re-
ports, &c.)

STATISTICS.

Population and Occupations.—The county of Worcester 
domains a variety of manufactures in hardware, carpet-
making, gloves, and china; and in 1831 it ranked the 
seventeenth in the list of the manufacturing counties, 
which had the largest proportion of their population engaged 
in non-agricultural occupations. The proportion of the agricultural 
was distributed as follows:—8024 employed in 
manufactures; 13,695 in retail trades and handcrafts; 
2065 capitalists, bankers, and members of the professions; 
there was an agricultural labour of 2.550 domestic servants, 
besides 1706 male and upwards, 3338; and there were 
1102 female servants. As the returns of Occupations 
under the census of 1831 are not yet published, we give 
the following details from the Population Tables for 1831: 
At Dudley, Stourbridge, and Old Swinford collectively, 
about 450 men employed at the forge, which make 
trivis, chains, and the heavier kinds of iron tools and 
machinery; at Wolverley, Cradley, Belbroughton, 
and Bredon, about 311 men engaged in gun-barrels, edge-
tools, and files; at Tredbridge 300 men make needles and 
sewing-hooks, 187 at Feckenham, and a few at Alvechurch, 
lock-with-Bradley, Inkerrow, and Booley; at Droitwich 
alt-pans are made; watch-springs, in small quantity, at 
the number of a few manufacturers of china, and the 
1000 or more of these, 1169 at Bromsgrove, 575 at Dudley, 
583 at Old Swinford, 152 at Cradley, 122 at Hatfield, 
at King’s Norton, 87 at Worfield-Wigom, 53 at Bel-
broughton, 60 at Stourbridge, and 42 at Pedmore. At 
Kidderminster (including the forefield of Kidderminster: 
and the chapelery of Lower Milton) 2500 men are employed 
in making carpets, and preparing materials for that manu-
facture; at Worcester, and at its suburbs, nearly 1000 men 
and a much greater number of females are employed in 
making gloves; the finest description of china-ware is also 
made at Worcester, employing about 50 men, and many 
females in the burning and other delicate operations; 
at Bewdley, King’s Norton, and Yardley various articles 
are made, in moderate amount, chiefly of the hardware 
kind.

If the registered baptisms, marriages, and deaths bore 
the same proportion to the actual population as in 1801, 
the population of Worcestershire, in the aforementioned 
years, would have been as follows,—51,739 in 1750; 72,285 
in 1800; 78,650 in 1810; 87,312 in 1870; 104,132 in 1700; 
and 102,910 in 1790. The population actually enum-

tated at the following decennial periods was as under:

From 1801 to 1841 the population increased 94,003, or 
40·2 per cent. In the three years ending June, 1841, the 
proportion of marriages to the population was 1 in 114; 
births 1 in 29; deaths 1 in 48; the proportion for Eng-
land being respectively 127, 51, and 40. In the same 
three years, the proportion of persons under 21 years of age 
under 21 years of age was 15 to 17 for women and 6 to 12 for men; 
and in England and Wales 17 to 9 for women, and 4 to 9 for men. (Fourth Report of the Registrar-General.) It 
appears from the Census Returns of 1841, that 183,964 persons, or 
76 per cent. of the population, were born in the county; 
46,175 persons, or 19.7 per cent., in other counties of 
England and Wales; 80 persons, or 1 person per 1000, in 
Scotland; 1411 persons, or 6 per 1000, in Ireland; 16 
persons were born in foreign countries, of whom 12 were 
British subjects born in foreign countries; and the place 
of birth of 1151 persons was not ascertained. The number of persons to a square mile was 322 in 1841. 
The number of parishes is stated to be 173 in the Popula-
tion Returns for 1841; and the population is actually given 
for 296 separate places. The population, &c. of 
each hundred and borough in 1841 is shown in the fol-

1831 the number of inhabited houses was 41,646, oc-
cupied by 43,512 families, and there were 302 houses 
lying, and 2096 uninhabited. 

3. Unemployed for the year ending March 31st, 1834, 
was 8,612. In the total difference in the sum expended 
in that year and 1827 was 38,022, or 29 per cent. 
Especially, in relief and maintenance, 18,345, or 22 per cent.; 
in suits of law, &c., 2572, or 66 per cent.; and in mis-
cellaneous expenses 2915, or 66 per cent. The number of 
poor-law unions is 13, comprising 218 parishes, which 
had a population of 211,365 in 1831: a number of these 
parishes are in the adjacent counties. Each of the under-
mentioned places is the centre of a union; and the sums 
expended in the year ending March 31st, 1834, under the 
heads of in-maintenance, out-relief, and establishment and 
relief, and salaries, were as follows:—

<table>

The expenditure for the year ending March 31st, 1834, 
was 8,612. In the total difference in the sum expended 
in that year and 1827 was 38,022, or 29 per cent.

1833 | 66,607 | 66,767 |
1834 | 60,500 | 60,635 |
The number of persons relieved in these unions during the quarters ending Lady-day, 1841 and 1842, were as follows:—In 1841—In-door, 2,298; out-door, 17,228; total, 19,527, of whom 5,050 were adult-bodied paupers; in 1842—In-door, 2,297; out-door, 15,749; total, 23,267, of whom 6,228 were adult-bodied paupers. The proportion in 1841 of 2.4; and in 1842 of 1.9, to the total population was 7 per cent., which is 2 per cent. less than the average for England.

The expense for maintenance and out-relief was 62,233l. for the year ending Lady-day, 1842, being an increase of 8 per cent. on the preceding year. There were 285 lunatics and idiots chargeable on the poor-rate in 1836, or 1 in 789; in England, 1 in 1033; and in August, 1842, the number chargeable was 284. In 1833-6 there were 1058 bastard children chargeable on the poor-rate, or 1 in 200 of the whole population; in England, 1 in 200. The number of illegitimate births in 1830 was 345, or 1 in 19; the proportion for England being 1 in 20.

The number affiliated in 1834-5 was 127, and 82 in 1835-6.

The annual value of real property assessed to the property-tax in 1815 was 799,600l.; property assessed to occupiers, 600,000l.; and the value of the rents, professions, &c., were assessed at 274,456l. In 1825-6 the centesimal proportion of the various descriptions of property assessed was:—land, 74.9 per cent.; dwellings, houses, 18.9 per cent.; mills, factories, &c., 9.7 per cent.; manorial profits, &c., 25 per cent. The net annual value of real property assessed to the poor-rate in 1841 was as follows:

<table>
<thead>
<tr>

The number of turnpike trusts, in 1810, was 22; the income from tolls, 39,631l.; parishes compositions in lieu of statute duty, 557l.; and total income, 42,884l., including 6,095l. borrowed on security of the tolls. The total expenditure for the same year was 35,600l., including a debt of 56,890l. paid off, and 4,501l. for improvements. The total mortgage debt amounted to 17,094l. In 1834 the debt was equal to 2.8 per cent. of the annual value of the county in England the proportion of income to debt being 4:4 per cent. and the proportion of unpaid interest to the total debt was 1.2 per cent.; in England 12 per cent.

The church-rates amounted to 5,035l. in 1839; and 7,024l. in 1842, applicable to the same objects, were derived from other sources, the amount from estates and rent-charges included under this head, being 1,106l. in 1832. The total 6,800l. was expended in 1839 for the purposes of the establishment, of which 5,041l. were for repairs of churches. There was a debt of 7,800l. on church-rate.

In 1841 the proportion of persons convicted to the population of the county, was 1 in 393; in England, 1 in 192.

Of 699 offenders (507 males and 192 females) tried in the assizes and sessions in 1842, there were 48 convicted with offences against the person; 58 with offences against the property committed with violence; 463 (including 25 cases of simple larceny) with offences against property committed without violence; 107 with malicious offences against property; 14 were charged with forgery and uttering base coin, and 46 with unlicensed trade. Of 416 persons convicted, 1, upon whose sentence of death was respited for life; 6 other offenders were also transported for 7, 10, 13 for periods above ten and not exceeding fifteen years; and 50 for terms of seven years; making 63 transported. None were sentenced to imprisonment for periods exceeding two years; 8 were imprisoned for a period not exceeding two years; 48 for above six months and not exceeding one year; and 284 for six months and under, and 15 were whipped. Of the 191 persons acquitted, 96 were found guilty on trial or in evidence; 58 were discharged; and in 21 instances there was no prosecution.

The total number of persons convicted, 45 per cent, were between the ages of 15 and 25; 16 per cent, between 25 and 30; and 16 per cent, between 30 and 40 years age. The degree of instructed in crime among those of the 23 cases: 200 males and 50 females could both read and write; 293 males and 44 females could read but not write; 19 males and 7 females could read but not write; and 4 males had received a superior education. The proportion of un instructed individuals in the county was in an average of several years was 98-5 per cent.; in England and Wales 89-3 per cent.

Savings' Banks.—There are nine of these institutions in the county, and the proportion of deposits to the population is higher than usual. The number of depositors is about 20 persons; and 1 depositor under 20l. in 30 persons. The average amount invested by all classes of depositors was 32l. in 1841; in England, 25l. The number of deposits and amount of deposits in each of the following years were as under:

**Lending libraries of books are attached to 35 schools.**

**Twenty-six Sunday-schools, attended by 849 children, are returned from places where no other school exists.**

**Twenty-three schools, containing 1828 children, were both Sunday and day schools.**

**The number of boarding-schools is fifty-four, and the scholars are included in the above returns.**

**The total number of children returned as attending Sunday-schools, and day schools, was 30,434; in 1841 the total number of children in the county between the ages of 5 and 10 was 19,312, and 17,690 were between 10 and 15; total, 37,002; or from 3 to 15 the total number of children in the county was 43,149.**

**On an average of three years, 1838-41, the number of persons married who signed the register with marks was 46 per cent. for the men and 61 for the women, the average for England being respectively 33 and 49.**

P. C. No. 1791.

**WORD.** [NOTION, NOTIONAL; VRBR.]
the diet of the independent labourer, but that of the majority of the persons who contribute to their support' (p. 31). And yet, by 30 Geo. III., c. 49, passed in 1790, the right of visiting any workhouse at all times of the day was conferred on justices of the peace and clergymen, and on their representation the overseers were liable to be summoned at quarter-sessions, when the justices could make orders and regulations for the remedy of any defects in the workhouse management. The chief recommendation of the Commissioners of Poor-Law Inquiry in 1833 was to unite parishes for better workhouse management. This is the origin of the Poor-Law Unions. As soon as the Poor-Law Commissioners were appointed, they immediately directed their attention to the general adoption of the principles of the system. They laid emphasis on the encouragement of pauperism, and for the establishment of independent habits amongst the labouring classes, is founded on the workhouse system. (Second Annual Report, p. 6.) Out-door relief is prohibited in a number of Unions. The Bench of Guardians and watch committee of the parishes occupied by paupers have been sold. New workhouses, capable of containing from one hundred to five hundred inmates and upwards, have been erected in nearly every Poor-Law Union, Boards of Guardians being assisted by grants of money, and the workhouse is added in twenty or more parishes. Rules and regulations for the government of the Poor-Law Unions have been framed by the Poor-Law Commissioners. In the first place, a suitable classification of the inmates is effected. They are at least divided into the following classes:—1. Women, and women's suckling infants. A separate ward or area is appointed for these children, 2, able-bodied men and youths above the age of fifteen years; 3, boys above the age of seven and under that of fifteen; 4, women infirm through age or any other cause; 5, able-bodied women and girls above the age of fifteen years; 6, girls above the age of seven and under that of fifteen; 7, children under seven years of age. The subdivision may be carried still further, at the discretion of the guardians, if the workhouse will admit of it. The maximum number of persons to be admitted in each house is fixed by the Commissioners. To each class is assigned a ward, and communication between the different wards is not allowed. Married couples are separated, exceptions being made in certain cases in favour of classes 1 and 4. The inmates under the age of any child in the same workhouse is allowed to see such child daily in a room appointed for the purpose. Mothers of children under seven years of age are permitted to have access to them 'at all reasonable times,' and so long as any mother is suckling her child she is permitted to it at all times of the day. Proper care is instructed in reading and writing and the principles of the Christian religion. The diet of each workhouse is fixed by the Commissioners, and it varies in different districts, regard being paid to the general dietary of the district. It is provided for in the first instance to do so by a pauper, the master or matron is bound to weigh the allowance of provisions served out to any pauper in the presence of the said pauper and two other persons. The accuracy of the following passage, taken from the 1st Section of the Poor-Law Commissioners' Report (p. 5), will not be disputed by any one who has visited a Union workhouse. The Commissioners say—'The necessary effect of our rules and regulations is to supply the inmates of a workhouse with wholesome food and sufficient clothing, a better bed than they are used to, a cleaner and a better ventilated room than they are used to inhabit, an immediate supply of medical attendance in case of illness, and to establish a degree of order and cleanliness in a labouring cottage. The provision made by the pauper has been accustomed to it; and it is owing mainly to the effect produced by the classification which is necessary to be observed in a workhouse, and to that degree of order and restraint which our rules encourage, that the workhouse principle is rendered really effective.'

The officers of a workhouse are—1, the master; 2, the matron; 3, a chaplain; 4, a schoolmaster and schoolmistress; 5, a medical officer for the workhouse; 6, a porter; besides six or eight assistants as the Board of Guardians may consider necessary. These officers are appointed by a majority of the guardians, but the Poor-Law Commissioners determine the amount of their respective salaries. The guardians may suspend the master, matron, chaplain, schoolmaster, schoolmistress, or medical officer for the workhouse, reporting such suspension, with the case thereof, to the Commissioners; and they may at once dismiss any other servant of the workhouse. The paupers of the several classes are to be kept employed according to their capacity, in such useful occupations as may be laid on refractory paupers by the master, with or without the direction of the guardians, by alteration of diet during a period not exceeding 48 hours, or by confinement for not more than 24 hours. The right to inflict punishments within a workhouse is by common law. Boys under 12 is to be confined in a dark room or during the night. Corporal punishment must be inflicted six days after the offence, and the particulars of the case must be entered in a book kept for the purpose; and no female child is to be punished for any misconduct. Paupers may quit the workhouse on giving 'a reasonable notice;' formerly a notice of three hours was required.

The admission of a pauper into a workhouse is effected by one of the following modes:—1, By a written or printed order signed by a relieving officer or overseer; 3, by the master of the workhouse, or the matron in his absence, or by the police without any order, in case of sudden and urgent necessity; 4, By Order of the Court of Petty Sessions, or by the police without acting as a member of the board; nor, 2, by a pauper of the peace; nor, 3, by a rate-payer of the parish. No pauper may bring cases of sudden necessity before the master of the workhouse, and he is bound to admit any case of sudden necessity. In the metropolis any person brought to the workhouse by police is at once admitted, if there is no suitable refuge, and will not be discharged until the expenses of maintenance is paid. The establishment charges of each Union workhouse are apportioned on a certain principle to the different parishes of the Union. The Court of Queen's Bench has decided that the workhouse is a board of rateable property. Under the Irish Poor-Law Act about 130 workhouses have been erected, and some of the largest will contain 2000 inmates.

(General Orders of the Poor-Law Commissioners; laley's Poor-Law Commissioners Acts; Annual Reports of the Poor-Law Commissioners.)

WORKINGTON. [CUMBRIA.]

WORKSOP. [NOTTINGHAMSHIRE.]

WORLD (UNIVERSAL). (Of recent German invention, for engraving on iron and glass.) Invented by a gentleman born at Peterborough in Northamptonshire, in 1730. He was a pupil of Grimaldi, and then of Bialot, a disciple of La Fage. Worldie is chiefly known for his etchings and engravings in imitation of Rembrandt; he copied almost all the work of his master, and there is a very good copy by him of the so-called Hundred Guilder piece. Worldie lived in black-lead, and with indiarubber, a medium, with extraordinary neatness. He made a set of one hundred and eighty beautiful drawings of the works of art. The designs were etched by himself, the plates of Rembrandt, amount to one hundred and forty; there are about seven or eight good portraits by him, likewise exact imitations of Rembrandt. Some of his admirers in his own time and since, have thought little of his etchings; Thomas Wolridge for the greater part of his life painted portraits in miniature; he afterwards with worse success performed them in oil; but at last acquired reputation and honor as etcher; the manner of oil paintings; he was a very easy task by the numbers of men who have counterfeited that master so as to deceive all those who did not have his works by heart. Worldie's imitations and his head in black-lead have grown astonishingly into his best piece is the whole length at St. John's College, MS. from Rembrandt: his print of the Theatre at Oxford and the act there, and his statue of Lady Dorothy Grafton, or very poor performances. Worldie's name was written prior to needlework with great skill. Worldie died at Hennemith in 1766.
Several and and This was Hbtoria De s-iarum, ft* known university. physic. university studied their Minnesingers May, (•Vita the physician studied 112, &c., give his bones the Antiquarian, and its great population, which in the time of the Hohenstaufen amounted to 60,000, and even after the Thirty Years' War was still 30,000, made it rich and powerful; but in the two next centuries its prosperity rapidly declined, chiefly in consequence of the strife in Germany and Sweden. In 1689 it was burnt by Melae, by the order of Louis XIV., and only the fine old cathedral resisted the efforts made to destroy it. Since then it has never recovered; some portions have been removed and the existing church is in a state of decay. The walls are large enclosures, some waste, some converted into vineyards and gardens, which were once covered with populous streets and fine buildings. Though the city offers therefore but a shadow of its former greatness, it is clear that the palace which occupied the site was already begun, and that since the beginning of this century there has been an improvement. The population was in 1801, 4800; in 1833, 6245; and it is now 8000 inhabitants, of whom the great majority are Lutherans. In 1010 there were only 70 Roman Catholic families, but in the 13th and 14th centuries these latter have been long established here, and enjoy privileges not allowed them in other parts of Germany. The most remarkable edifice is the venerable cathedral, which was founded in the eighth century, but has been restored and enlarged during the last century. It was finished in 1016. It is a plain Gothic building, with two towers at each end.

Worms is the seat of the provincial tribunals and of the consistory, and a manufacturer of paper, tobacco, and tobacco papers, and a good trade in corn, cattle, and wine grown in the vicinity, of which that called 'LIEBHOFER MILL' (or 'Our Lady's milk') is so named from its being produced in the neighbourhood of the Liebfrauenkirche (The church of Our Lady).

WORMS.

WORMS, a town in the province of Rhineland, in the duchy of the Palatinate, militarily in the Empire, and ecclesiastically in the Electorate of Trier, 26 miles long, near the left bank of the Rhine, which formerly touched its walls, in a beautiful country, called by the Minnesingers the Wonnegau (the land of delight). The city is said to have originated with a Roman fortress, called Bobitamogus, or Augusta Vangionorum. After its destruction by the Vandals and Huns, it was rebuilt by the Franks about 475; it was called Worms, and became the seat of a count (Gaugraf), and subsequently of the dukes of Frisia, who styled themselves Counts of Worms. It was the seat of the residence of at least (for a considerable time) of Charlemagne, who held in his vicinity those primitive legislative assemblies which, meeting in May, were called Mai Lager, or Champs de Mai, in one of which assemblies the war with the Saxons was resolved on. The privilege of the Frankish and Carolingian courts continued here.

Several diets of the German empire were held at Worms, among which were those of 1122, at which a convention was concluded between the emperor Henry V. and Pope Calixtus II.; that of 1455, which abolished the right of primate; and lastly, that of 1530, which amounted to a declaration of war against Charles V.
which is esteemed the finest specimen of historical poetry in the language. When the duchy of Warsaw was established in 1808, he was made both a member of the council and dean in the chapter of the cathedral; and through the influence of the Czartoryski family, was soon necessary for his new position. He was seen to the bishopric of Cracow in 1815. Twelve years afterwards the emperor Nicholas raised him to the dignity of archbishop of Warsaw and primate of all Poland; but he was then labouring under infirmities which induced him to go abroad for medical advice, and while thus travelling, he died at Vienna, October 4th (o.s.), 1823.

Besides his Sidylla, he wrote several other poetical compositions of merit, and one of them, 'Sejm Wislicki,' or the Diet of Wilanow, though only the fragment of what was intended to be an epic, was found by some to display greater power than his first more celebrated production. His poetical fame however is fully rivalled by that of his prose writings. 'His sermons, speech, the author of the 'Letters on Poland,' excels in a boldness of conception akin to Pope of Heberd, and seem to be the instantaneous emanations from the pure source of religious morality—the more impressive, as they are couched in an energetic dithyrambic language, like that of Homer. His poetical advice, and while thus travelling, he died at Vienna, October 4th (o.s.), 1823.

Ten years later, on the downfall of Bestuzhev-Rumian, he became chancellor, and, so long as he held that arduous office, showed superior ability as a statesman; but after Catherine II. had ascended the throne, his influence waned, at least the enmity of several of the more powerful nobles towards him showed itself in such manner, that he sought to avoid worse consequences by absenting himself, as formerly, under the pretext that travelling was necessary for his health. Such an excuse was pointed to as his deputy in the meanwhile. On his return to Russia, finding his opponents no better disposed towards him than before, he solicited permission to resign office altogether, and retired to Moscow, where he died Feb. 13th.

Woronzew had many of the qualities that mark a superior statesman, and was in other respects a man of a noble character. He patronized the literature of his country in the person of Lomonosov, to whom he erected a monument. He also supported and advanced all the younger men and poets who had left. Count Michael's only offspring was his daughter, married to Count Alexander Strogonov; but he was the uncle of three females, the most distinguished of their time for beauty and for talents: these were the daughters of Countess Polyanovskaya, and Catherine, the less eccentric than accomplished Princess Dashkov. (Sensitizopoliticheskiy Lekakon; Beatus-Kamenenskiy, Somozna.)

WORSLEY, SIR RICHARD, Bart., was born in 1751, in the Isle of Wight. His father was Sir Thomas Worsley, and Richard succeeded to the title when he was about eighteen years of age. He soon afterwards travelled on the Continent, and remained a considerable time at Rome, where he purchased a variety of pieces of sculpture and other remains of ancient art.

Sir Richard Worsley, after his return to England, sat in the House of Commons for many years as one of the representatives of the borough of Newport in the Isle of Wight. He was comptroller of the royal household to George III., and also held the office of governor of the Isle of Wight, where he died in 1803.

Sir Richard Worlsey published a 'History of the Isle of Wight,' at Bath in 1815, in 8vo. The history is natural, civil, military, commercial, and European; but except in mere matters of historical detail, most of them dull enough. Worsley's work has been praised by Sir Henry Englefield's 'Description of the Isle of Wight,' and by Sir Walter Scott's 'Woodes,' and some are said to be written by Lord Byron, who was at his service while abroad. The greater part of this work was published by Sir Richard Worsley in London, folio. Sir Richard Worsley also published 'Museum Worsleiinum or, a Collection of antique Relics, Bustos, Statues, and Gems; with Views of Places in the Levant, taken during his tour. 1789, and published in London, in 1790.' He was in the arrangement and description of his collection by Ennio Quirino Visconti. It was published at Rome, and at the time of its publication was considered to be a type of any which had issued from the English press. Very copies were printed; some authorities say only fifty, but others two hundred and fifty, and the total expense for Richard was about £2,000.

WOOTON, EDWARD, was born at Oxford in 1548. He studied at Christ Church, and took his Bachelor's degree in 1513. He was subsequently appointed to a fellowship at Corpus Christi College. In this position he remained till 1520; he then travelled into Italy, and having visited the principal cities in his way, arrived in Vienna in 1523. He took his degree of Doctor of Medicine at Oxford in 1525, and became a Fellow of the College of Physicians of London. He was afterwards appointed physician to Henry VIII. He devoted much time to the study of natural history, and published at Fano in 1562, a work entitled 'De Differentia Animae.' This work is spoken highly of by Gesner. It does not contain any new matter of his own, but was an e and in the state, and has been used for many years. He began a history of insects, but this work was never published. He died in 1564. (Hitchin's "Biography Medica.")

WOTTON, SIR HENRY, was born 30th March, 1568. O. S. was a gentleman in the household of Isaac Walton, called Bolton or Buerton Place, in the more modern accounts written Boughton Hall, in the county of Boughton-Malherbe, in the county of Kent. Here he resided, several of whom had held distinguished engagements in the state, as well as in the Church. His father, Thomas Wotton, Esq., was twice married: first to Elizabeth, daughter of Sir John Maitland, Knight, by whom he had three sons; Edward, knighted by Elizabeth I. and in 1603 raised to the peerage as Baron Wotton. He was knighted by Elizabeth; secondly, to Eleanor, daughter of Sir William Finch, of Eastwell in Kent, and widow of Robert Martin, Esq., of the same county, by whom he had Henry, the subject of the present notice.

His grandfather, Sir Henry, stated to have been his brother; he then had a resident tutor; afterwards he was sent to Winchester school; thence, at the age of sixteen, he was removed to Oxford, and admitted a gentleman-commoner of New College; finally, two years after in 1587, he was returned to Queen's College, and was a member of this society he composed, at the desire of the provost, a tragedy entitled 'Tancredo' (in which Iago is not stated), which, according to Walton, was greatly admired. But it soon after became apparent that about the twelfth year of the reign he proceeded Master of Arts, on which occasion he read with great applause three lectures, in Latin, on the eye, and Woot, although he could not discover any record of his admission to the degree, that on the 6th of June, 1588, he was profe
grant, or petition, to the University, to be admitted to the
reading of any of the books of Aristotle's Logic; which
writings...probably for his degree of A.B. After
his optical lectures, Wotton tells us, he was taken into
the closest intimacy by the learned Italian Alberic Gentili,
then professor of the civil law at Oxford; and from him he
acquired not only a large knowledge of both law and
mathematics, but an accurate knowledge of the Italian
language. In the next year, 1586, his father died,
leaving him with three younger sons an annuity of a hundred
marks; and Wotton intimates that this event prevented his remaining
so long at Oxford as his friends once intended; afterwards
he was called for the services of the law, till after his father's death; at which time he was about
the twelfth year of his age...and then laid aside his
books and betook himself to the useful library of travel.
But one of his letters to Lord Zouch, dated 10th July,
1585, says that he had been three years upon his
travels. Wotton goes on to state that he was abroad almost
nine years, one of which he spent in France, and most of
that in Geneva, where he became acquainted with Theos-
dos Beza (then of great age), and with James Camonbin
(induring whose time Wotton had been lodged: 'Three
of the remaining eight years,' it is added, 'were spent in
Germany; the other five in Italy...where, both in
Iona, Venice, and Florence, he became acquainted with
the most eminent men for learning and all manner of arts,
as picture, sculpture, music, oratory, geometry, em-
manual arts, even arts of interior nature; of all which he
was a most deep lover; and a most excellent judge. He
retired out of Italy into England about the thirteenth
event of May, 1587, and therefore spent the rest of the
year at person and comportation; for indeed he was of a most
self of stature, and of a most persuasive behaviour...'
But notwithstanding the particularity with which all this is
related, there must be some error. The account would
run that Sir Edward Wotton had been elected to the Council
of Ireland, at the earliest, and he was now, his biographer
proceeds to inform us, taken into the service of the Earl
of Essex as one of his secretaries, and 'did personally
attend the earl's councils and employments in two voyages
afterwards, at the ears of Lord Mortimer, who was in the
early last into Italy; that voyage wherein then he did
most provoke the queen to anger...'
Now Essex set
out on his first expedition to Spain in June, 1586, and on
his second in August, 1587; both dates antecedent to that
when Wotton had been elected to the Council of Ireland.
It is probable that Wotton either went abroad sooner,
or did not stay away from England so long as his
biographer makes him to have done. Essex went to Ire-
land in March, 1589, and returned in September of the
same year. Wotton was then in Paris, and probably met
him. Wotton tells us, as soon as he heard of Essex's second approach and
commission to the Tower, 'did very quickly, and as pri-
vately, glide through Kent to Dover, without so much as
looking toward his native and beloved Boston; and was,
by the help of favorable winds and liberal payment of
the mariners, within sixteen hours after his departure from
London set upon the French shore.' There is no reason
however to suppose that Wotton was involved in the earl's
adventure, like his brother secretary Cuffe, who was hanged.

It must be observed in consequence of his residence among his old friends at Florence, whence
after some stay he went on a visit (called his fourth) to
Rome, returning to Florence, Wotton says, 'about a year
before the death of Queen Elizabeth,' which would be
about the year 1589, and was dismissed by the earl's
demand: 'It appears to have been in this first year of his
residence abroad that he drew up his treatise entitled The
State of Christendom, giving a perfect and exact discovery
of every political and secret Mysteries of State treated,
in most of the Courts of Europe; with an Ac-
account of their several Claims, Interests, and Pretensions,'
first printed in Bologna in 1592, and again in 1597. It was
immediately after Wotton's return from his visit to Rome,
that the nascent genius of Wotton announced him as the Biographer of the crown. He wrote several letters discussing a design to take away
the life of King James of Scotland, and on the advice of
his secretary Signor Vieta, who was an intimate friend of
Wotton, resolved to employ Wotton to communicate the
affair to James, and accordingly, says Wotton, 'acquainted
him with the secret, and, being well instructed, dispatched
him into Scotland with letters to the king; and with
those letters such Italian antidotes against poison as the
Scots till then had been strangers to.' This mission proved
the foundation of Wotton's after fortunes. Calling himself
Octavio Baldi, and assuming the character of an Italian,
he proceeded by way of Amsterdam through Norway, and
found King James at Stirling. Having announced himself as an ambassador from the duke of Tuscany,
he was soon admitted to the royal presence through the
hand of Lord Grey, a gentleman of the bedchamber, not
however without having been questioned when he came
to the presence-chamber door to lay aside his long rapiers.
Three or four lords were standing distant a few
steps from the chamber; on seeing whom he hesitated; but
James desired him to be bold and deliver his message,
which he would undertake for the secrecy of all that were
present. 'Then,' continues the narrative, 'did Octavio Baldi
deliver his letters and his message to the king in Italian;
which, when the king had gratefully received, after a little
manner Octavio Baldi steps to the table and whispers to the
king in his own language that he was an Englishman, be-
seeking him for a more private conference with his maj-
esty; and that he might be concealed during his stay in
that nation; which was promised, and really performed by
the king during all the king's stay. Wotton, however,
two months, all which time was spent with much pleasantness
to the king, and with as much to Octavio Baldi himself as
that country could afford.
A few months before Wotton's return to Florence news
arrived of the death of Queen Elizabeth; upon which, by
the grand-duke's advice, he immediately proceeded
England, where he found that James had not forgotten
him, but had already been making inquiry after him of his
friends in England. When Wotton arrived at London, the
king upon his arrival in London found holding the post of
comptroller of the household. Wotton immediately
received the honour of knighthood, and the next year (1604)
was sent as ambassador to Venice, accompanied by Sir
Robert Cuffe, as his secretary. Wotton stayed for a few
months at Augsburg, on his way whither, that he wrote in the album of a German friend his famous
definition of an ambassador—'Legatus est vir bonus
peregre missus ad mentiendum reipublicae causa' (an ambas-
sador is an honest man sent abroad to—'It is a com-
monly rendered, sent to lie abroad—for the good of his
country); which eight years after was published by the
learned and rancorous Caspar Schiapinnis, in a work against
King James, as a principle of the religion professed by that
monarch. Wotton's letters were immediately used by the
author, who was writing a history of the peace of
Utrecht; and another letter on the subject in violent abuse of Schiap-
nis, which Wotton wrote to a friend, Marcus Velsenus,
one of the chancellors of Venice; and another
writings. Wotton saying nothing of the equivoke in
the English term bin, which is a made principal point of
the story as it is commonly told; nor indeed does it appear
how he could have had any such double meaning in view
while writing in Latin. He had returned from this first
mission to Venice before he wrote his letter to Velsenus,
which is dated at London, 2nd December, 1612. The writer
of his Life, in the 'Biographia Britannica,' says that he
came home in 1610, and conceives that he was probably
therefor the just of the present and suitably furnished
parliament, which was sitting at Westminster. There is no
printed list of the members of this parliament, but Sir
Henry, in a letter dated a few days after its dissolution,
speaks of the late House of Commons by the expression
'our house.' At this time Wotton was engaged on a mission to the United Provinces, and on his
return in the beginning of the following year he was re-ap-
pointed to the Venetian embassy. He resided at Venice
three years, and then returned to England in July, 1615, with the
hope of being appointed to the place of secretary of state, vacat
by the death of Sir Ralph Winwood. But that event had
taken place a year and nine months before; so that here
again there is probably some mistake. According to the
ancient author, he was in 1641, the following year, sent
away abroad, first as ambassador extraordinary to the
duke of Savoy, and then several times into Germany upon
the affairs of the elector-palatine; 'after which,' it is
added, 'being remanded a third time to Venice, with
certain orders to return the round his business there,
returned not to England till the year of King James's
death,' that is to say, in 1625. But he was certainly back
here by 1624 at the latest; Walton says that he came to
London 'the year before King James died;' and even the
second edition of Biographia Britannica, proceeding some-
what inconsistently, to inform us that 'not long after his
arrival, upon the death of Mr. Thomas Murray in 1623, he
succeeded him in the provostship of Eton College.' Wal-
ton's narrative implies that this place was given him by
King James, who had previously, it seems, granted him
the reversion of the place of master of the rolls, then held
by Sir Julius Cesar; but Wotton, who was in a state of great
pecuniary necessity, required, we are told, a present sup-
port, and very gladly resigned his reversion upon getting
a grant of the provostship.

Sir Henry Wotton's principal writings are contained in
the two volumes entitled Religion Woessanae, first pub-
lished by Isaac Walton, with a Life of the author, in 1651,
and afterwards, with additional matter in each
impression, in 1654, 1672, and 1685. The principal pieces
of which it consists are—a treatise, long held in great esteem,
entitled 'Disputandni pruriitius ecclesiae scabies;' a second
edition published in London, in 1640; 'A Philosophical Survey
of Education, or Moral Architecture' (dedicated to Charles I.);
Characters of some of the English kings (in-
tended as materials for a History of England); a Latin
Panegyric Address to King Henry, which, as usual, never
reached Scotland in 1633 (first published in folio, at London,
in 1633), with an English translation by a friend of the author:
'a Parallel between the Earl of Essex and Villiers, Duke of
Buckingham,' first published in 1610, at London, in 1622; an
'Address of the View and Death of the Duke of Buckingham'
(first published in folio, at London, in 1642); some religious
Meditations; and a number of Letters and Poems. More
of his letters are in the 'Cabala;' and there are some poems
attributed to him, especially the 'Reliquiae,' a poem on
'State of Christendom' has been already mentioned.
The literary reputation of Sir Henry Wotton rests now prin-
cipally on his poetry, which, although consisting only of
some short pieces, is distinguished both by its general cor-
rectness, and in its happiest passages by a dignity of
thought and expression scarcely attained by any of his
contemporaries. In his lifetime he was famous for his
pointed sayings; but here the manner, as usual, probably
went as far as the matter in creating the impression that
was formed of him. There seems to have been no very
damaging or deep in his favourite verse, his author-
ship of which he directed should be recorded on his tomb,
'Disputandni pruriitius ecclesiae scabies;' 'The Ith of
disputation is the scab of churches.'

WILLIAM, a D.D. by Ainslie, is chiefly remarkable as an
instance of strength of memory, and early progress in the
acquisitions mainly dependent upon that faculty, was born
13th August, 1696, at Wrentham in Suffolk, of which
parish his father, the Rev. Henry Wotton, was rector.
When he was five or six years of age he had,
under the tuition of his father, who was a
good scholar, attained considerable facility in reading and
translating the Latin and Greek and Hebrew. Sir Philip Stapyl-
son, who knew him in a letter written about this time to
Ray, the naturalist, says, 'He is not yet able to parse any
language, but what he performs in turning the three learned
tongues into English is done by strength of memory; so
that he is ready to mistake when some words of different
signification have a very remote connexion. His father has
taught him by no rules, but only uses the child with
him, as if he were a child of five, teaching him to repeat
in remembering words: some other children of his age
seem to have as good a fancy and as quick apprehension.
In April, 1766, some months before he was ten years old,
the school was shut up for the summer, and he went to
London, where he made rapid progress, not only in the languages, given by
Chaldæa, Syriæ, and Arabic to the Latin, Greek, and
Hebrew, but also, it is asserted, in logic, philosophy,
theology, chronology, and geography. In 1769 he
finished his studies, and, being recommended to Dr.
Gilbert Burnet, then prebendary of the Rolls, and intro-
duced by him to all his learned acquaintances. Among other
persons whom he visited was Sir John St. Asaph, who,
as was highly pleased with a list of memory which Wotton produced, repeating
verbatim a sermon preached by the bishop, that he took him with
him to St. Asaph, and kept him there for some
weeks, paying him handsomely out of his
library. He then returned to Cambridge, where, by
the interest of Dr. Turner, bishop of Ely, he obtained a
chancery clerkship in St. John's, and where he took his degree of M.A.
in 1675. He then lived at Oxford, where, in 1679,
Lloyd gave him, with the income of Llandilo in
Bergshire; and he was soon after made chaplain to the
Duke of Nottingham, then secretary of state, who, in 1693
presented him to the rectory of Middleton Keynes in
Bedfordshire.

In 1694 Wotton published his first and best remembered
work, his 'Reflections on Antient and Modern Learning,'
which is a defence of the superiority of the antients
against the moderns. He answers to Sir William Temple, who had shortly before
him, in 'The Antients and Moderns,' to the question, in arguing against Pernault's
'Parallels de Anciens et Modernes,' which had appeared at Paris in 1687.
Wotton's performance is famous both for harsh
defence, called forth from Swift in his 'Battle of the Books,'
and for his friendship towards disputants, and his
enthusiasm for the controversy about the so-called
'Epistles of Phalaris' on the authenticity of the
'Epistles,' which had been attacked by
Temple, was disputed by Wotton; and it was in an
appendix to the second edition of the 'Reflections,'
written in 1697, that Bernard住宿, one of the first
drafts of his celebrated 'Dissertation,' demonstrating the
genuineness of the 'Epistles,' with a special reference to
his edition of them brought out by the Hon. Charles
Montagu, and distinguished himself more by his
rather than accuracy or profoundness of learning, and
the judgment was of no remarkable power; the inherent
of the 'Reflections,' accordingly, is not considerable.
Of many other books which he afterwards published
there is nothing either in life or death of any note.
Hickes, perhaps, of his 'View of Hickes's Archaeological Travels
of the Antient Northern Languages,' which was first
drawn up by Hickes himself, and was published in 1698;
and of which a second edition appeared in 1707.
Wotton's edition of the ancient Welsh laws, with a Latin
translation, which appeared in a folio volume in 1730, after his
death, under the title of 'Cyseithiriu Hywel Dda, as earl; Lege-
Wales, edited by Anœurn Owen, Esq., Oxford,
Lond. 1841. Wotton acquired such a command of the
Welsh language as to be able to preach in it. In
1727 he was a canon of the diocese of St. Asaph,

died in
WOUNDS, in Surgery, are solutions of the continuity of the soft parts of the body effected by some external agent, and attended with a greater or less amount of bleeding.

Wounds vary in their character according to the kind of instrument by which they have been produced, as well as the greater or less amount of force with which it has been applied. In order to facilitate the description of treatment surgical writers have divided wounds into several kinds. Thus they are spoken of generally under the terms incised, punctured, contused, lacerated, poisoned, and gunshot wounds. Wounds of particular parts requiring peculiar treatment are also described, as of the head, throat, chest, &c.

Incised wounds, cuts, or incisions are produced by cutting instruments, and are free from contusion and laceration. Punctured wounds or stab wounds are caused by pointed weapons, as bayonets, lances, nails, pins, &c., penetrating deep into the flesh. Contused and lacerated wounds are produced by the violent application of hard blunt and obuse bodies to the soft parts; and under this head might be included gunshot wounds. Poisoned wounds are those which are complicated with the introduction of a poison into the wounded part. Wounds are more or less dangerous according to the extent of soft parts they involve, the parts they occur in, and the state of health of the individual wounded. In small wounds, unless poisoned, the system generally suffers little in consequence, but when a large amount of soft parts are injured, symptoms of fever come on from twenty to thirty hours after the receipt of the wound, which require attention on the part of the surgeon, as, according to the constitution and circumstances of the patient, the fever may vary greatly, and require opposite modes of treatment. This fever is called symptomatic, and in most cases is inflammatory.

Incised Wounds. — The effect of a cut on any part of the body is to produce a gaping space, from which blood in most cases issues, and pain is felt. The blood arises from the blood-vessels of the part having been cut through or wounded, and the pain is caused by a similar injury to the nerves. The amount of blood that issues from a wound, as well as the pain, will always depend upon the nature of the part which is injured. Some parts of the body are very copiously supplied with blood-vessels which have few nerves, and vice versa. So that neither pain nor bleeding is constant according to the size of the wound. The immediate danger of incised wounds does not so much arise

In the perpendicular tube, which resists the egress of the gas.

We have already observed that various modifications of this apparatus have been proposed, an account of which may be seen in different chemical treatises: the above description is taken almost entirely from Dr. Henry's Elements.'
the skin about the wound cannot be kept too clean and free from impurities of every kind.

**Incised Wounds.**—These wounds are dangerous from their depth, and the internal egression of serum and blood which usually attend them. In consequence of this, these wounds are frequently followed by severe inflammation and suppuration. These results used to be attempted to be obviated by the practice of dilatation. This however is severely punished by the appearance of large collections of pus and inflammatory exudation over their surfaces. Setsone is recommended by the French surgeons for these wounds, but there are so many objections to it, that they are seldom used by surgeons in this country. Whether these wounds are unite by the first or second intention, they require to be healed upon the same general principles as incised and gunshot wounds.

**Incised and Lacerated Wounds.**—These result from the lollation of blunt, obuse, hard bodies, being forcibly driven against the living textures. Although these wounds may occur independent of gunshot, it is in the class of called gunshot that the best examples of lacerated and incised wounds occur. The rapid introduction of powerful machinery into the manufactures of this country renders incised and lacerated wounds of very frequent occurrence in our large towns. In these wounds there is seldom much bleeding, arising from the coaptation of the arteries becoming twisted and doubled up by the force of their removal and the much more liable to have been given by the bodies in them than incised wounds. Such wounds seldom unite by the first intention, but in their treatment this object should always be kept in view, as frequently portions of the wound may be induced to unite. During suppuration proceeding on, the same plan of treatment must be pursued as when these processes occur in incised wounds. The constitutional symptoms arising from these wounds are generally more severe than from any others, and require attention. Symptomatic fever must be treated according to the same general principles laid down for the treatment of fever. [Fever.] Another consequence of these wounds is that dreadful state of the nervous system called tetanus [Tetanus], which often resists all kinds of treatment.

**Poisoned Wounds.**—The principal forms of this class of wounds seen in this country arise from the bites of rabid animals, pricks and cuts received in dissention, and the bites of vipers and the stings of insects. The bites of rabid animals are unfortunately too common, and often in this country require the attention of the surgeon. When the poison is introduced into the system it produces the fearful disease known by the name of hydrophobia, for which medical science has not hitherto found a remedy. [Hydrophobia.] It is seen that all persons have been bitten by cattle, horses, or wolves in a rabid state, the wound should be immediately excised and the nitrate of silver (lunar caustic) applied to the wound.

**Dissecting Wounds.**—Under this head may be included all the accidents which animal and human hands exposed in the examination of the dead human body, but all those wounds after which ill consequences ensue, in which there is reason to suppose some poison generated. In an animal organisation has been introduced into the system. It is still sometimes discussed in books on surgery, as to whether the effects following these wounds are produced by a peculiar poison or are only the result of a slight wound in a constitution predisposed to disease. The first effect is the ill effects of these wounds among the medical men, as compared with the large number of persons liable to prick and cutting their fingers, must decide this question in favour of the existence of a poison. It is not, however, as is generally supposed, that putrescent and stinking substances advanced in decomposition are most injurious, for it is generally found that those sequelae which follow wounds from recent bodies, especially of persons who die of putrescible putridities. The consequences following these cuts are uneasiness and fear of the wound. Far is the absorbing process upon the arm begins, there is pain felt in the arm, and in the glands of the axilla; these symptoms are attended with more or less fever, and generally great anxiety. These symptoms sometimes increase, the cellular tissues of the arm and side become much reddened, those of the throat are perhaps the most common, and require the most prompt attention. These wounds are generally the result of attempted suicide, and vary in extent according to the greater or less determination of the individual at the time, and effects of the wound. The first thing to be attended to in these cases is to cut the hamstring, which must be done by passing between the wounded arteries.

**Wounds of particular parts of the body.**—When any part of the body is considered as being wounded, questions frequently arise as to the treatment, which can hardly be answered in general principles; hence the wounds of particular parts of the body require consideration. Wounds of the scalp are frequently accompanied with the effects of shock, or diverging a narrow arrow, or the violence of the wound. Wounds of the scalp are also frequently attended with severe inflammatory symptoms, and no injuries of the body are more attention and close watching than those of the scalp. If not treated with the greatest possible care, those of the throat are perhaps the most common, and require the most prompt attention. These wounds are generally the result of attempted suicide, and vary in extent according to the greater or less determination of the individual at the time, and effects of the wound. The first thing to be attended to in these cases is to cut the hamstring, which must be done by passing between the wounded arteries.
When the trachea is opened, the entrance of blood into the lungs should be avoided as much as possible, as its existence there as a foreign body may bring on inflammation of the lungs. When a wound occurs in the larynx above theematicus, every attention should be paid to removing anything that may irritate the glottis or prevent the free passage of air to the lungs. When the oesophagus is wounded, all the food of the patient should be administered by means of a tube passed through the mouth, nostrils, or the wound when opened; and if this is done for a cut-throat will attempt immediately to bring the edges of the wound together by sutures. If this be done, the chances are that the patient will die of suffocation, and death is certain if the wound has been lacerated, an attempt should be made gradually to bring together again the divided parts. This is frequently done with the most perfect success, and sometimes the very worst cases of cut-throat will recover. It will however happen that one of which he immediately afterwards the surgeon to meet all the difficulties that will arise in the treatment of cases where so many important organs are involved.

Wounds of the chest become dangerous when they involve the ribs of the thorax, and several important questions arise out of the nature and extent of these wounds. The most important complications are these: 1. The entrance of foreign bodies into the cavity of the thorax; 2. The injury of one or more of the intercostal muscles; 3. The fracture of one or more of the ribs; 4. The occurrence of emphysema from the wound; and 5. Extravasation of blood in the cavity of the thorax. Wounds of the abdomen, when superficial, require the same treatment as wounds generally. In pene-

(Woooverman, Philip, one of the most popular of Dutch, and after, in his turns, two or three years, he received his first instructions in art from his father, Paul Wouwerman, an obscure historical painter. He was instructed also by John Wynants of Haarlem, but his style was quite original, and was indebted little if at all to the works of his instructors. Wouwerman lived always at Haarlem, and he is generally considered and reported to have been one of those unfortunate painters who depended entirely upon the liberality of picture-dealers, and to have made his patrons rich while he lived in poverty. This does not appear to have been the case with the painter who states that Wouwerman's pictures rose immensely in value after his death, but that he was nevertheless a fortunate painter; and, in corroborated of the latter part of this assertion, he states that he gave his daughter 20,000 florins (Hendrick van der Heurn) was the son of his family, and that there is no truth in Hoobraken's report that he gave his daughter 20,000 florins dowry.

Wouwerman died in 1688, aged 48, and he was so dismally and piteously visited against the day of his death, and that it was so miserable and wretched, that he was only paid for his services in the field of battle, and a less charitable reason assigned for this destruction, it is feared they might fall into the hands of his brother Peter Wouwerman, who painted similar subjects with himself; a second account is, that the designs and studies which he burned were not his own, but principally Peter Leet's, and that he destroyed them that it might not be known how much he had made use of the labours of others. None of these stories may be true, but they at least show that Wouwerman, like many other men of genius, had his foils as well as his friends. Wouwerman must un-

(1.) WRAGBY. [Lincolnshire.] Wraingle, Carl Gustaf, son of the Swedish general Hermann Wrangell, governor of Livonia, who died July 10, 1664, and Peter, a military commander, was born at Skokiester on Lake Malaren, December 13, 1613. Sent abroad at an early age to acquire foreign languages, he passed a whole year in Holland, where he gained considerable insight into nautical matters and shipbuilding, and, impressing with his admiringly designed and coloured, and most appropriately introduced; they are also distinguished by the same rich transparency of colouring which characterizes the landscape part of his pictures.

Wouwerman's pictures are very valuable, and, notwithstanding his short life, are very numerous: one or more specimens are in almost every good collection in the northern parts of Europe. Many however of his brother Peter's are attributed to him, but though very similar to one another, they are not in all respects like. His pictures of horses are very inferior. He had another brother, John, who was a good landscape-painter. John died in 1680, and Peter in 1683.

Hoobraken, Schouburg, &c.; D'Argenville, Vie des Peintres, &c.)
The substantive Wrangler is hardly ever used, except as qualified by a date, and although the term has passed, the functions of the Bachelor's degree in the university of Cambridge (the word is unknown in Oxford) with such credit as to have had its name inscribed in the highest list, or of wranglers. Of these the first in merit is the Senior Wrangler, to which a candidate not accepted to the presidency of the University is apt to confound Wrangler with Senior Wrangler, that is to imagine that any one of their friends who may have obtained a wranglership must necessarily be the first man of his year. The second list is that of Second Wranglers, and the last the Third, or Junior Optimes. All who are in these three lists (which are collectively called the Tripos) are said to take the Bachelor's degree with honours, or to go out in honours; the first entitled to a college, abbreviated into the Pol, though they equally take the Bachelor's degree, are not supposed to be honoured. But in point of fact, the last of theJunior Optimes, or the last on the list of honours, has always been considered an unfortunate person, and by the phraseology of the word "wooden spoon" has long been attached to his place. It is not as if all were examined together, and the honours were selected out of the whole list: those who wish to go out in honours declare their intention and are examined separately; so that it frequently happens that the first of the honours-goers is a person of very inferior attainments to many at the head of the unhonoured multitude. With regard to the fictitious terms current in the universities, it should be known that all the seceders,"the heads of houses, professors, &c., generally adduced as nicknames invented by the students, and the term "Wooden Spoon" which is applied to these nicknames, is said to have been invented by a student with a wooden spoon, after an examination as it is styled in the grace of the Senate which established it, should use those words instead of "the little go, a term which was borrowed from the Oxonians as soon as the grace was passed.

There is no history extant of the original introduction of the terms, wrangler, senior optime, and junior optime. Hume, whose history of our universities has just been translated by Mr. Newman, says that every attempt he has made to obtain information on this subject has made him giddy with headache. A Cambridge man, however, finds no difficulty in seeing how the word was used, as applied to the manner in which an examination (not a public disputation) is passed. The examination which takes place in January, and of which a young man is said to "take his degree" (because in fact he then does all that will be asked of him, the rest having degenerated into mere form), is not an examination for the B.A. degree, but for the right of being admitted to perform the disputations necessary for a degree. All degrees were originally gained by disputations; the substitution of an examination, to see whether the candidates were fit to dispute, is a

A Cambridge man, however, finds no difficulty in seeing how the word was used, as applied to the manner in which an examination (not a public disputation) is passed. The examination which takes place in January, and of which a young man is said to "take his degree" (because in fact he then does all that will be asked of him, the rest having degenerated into mere form), is not an examination for the B.A. degree, but for the right of being admitted to perform the disputations necessary for a degree. All degrees were originally gained by disputations; the substitution of an examination, to see whether the candidates were fit to dispute, is a

thing of comparatively modern times. The vice-chancellor, when he is examining candidates, admits the candidates not to the Bachelor's degree, but to suppose themselves to be entitled to it, and the person thus admitted is called a questioner. The question, which is of some interest, or of some other questioner and is the occasion for the examiners, and the person thus given to one of the fellows of whose duty it is present, the candidates of his college to the vice-chancellor. On the Thursday after Midsummer, the vice-chancellor declares all the questioners (who in the interval have been made admissible to the examination) for the next time, and assumed the name of the University. In the case of Tripos, 1747 for dollars: but the wranglers and some optimists form one list till 1732 inclusive. It is said that the regular order of previous years cannot be ascertained.

The British species of Wrasses belong to three subgroups of Labrus, viz. Labrus properly so called, the species which have the margin of the preopercle entire, and are opercular and opercular. The first species is Labrus, in which the first dorsal fin is divided, and the head is entirely smooth and scaled; the other is Crenilabrus, in which the preopercle has a distinct margin, and the cheek and opercles are scal.

The species are extremely variable in colour, and the species presented the most vivid orange, blue, green, and bright yellow being common in the genus. These colours are most beautiful in spring, just before the spawning season. They frequent the crevices of rocky shores, living among the larger weeds, and feeding on crabs and other crustacea. At articles of food they are not exclusively valued in British, the fish wanting firmness and flavour. In the Mediterranean however they are constant ornaments of the fish-market. The species comes to growth to anything from 8 to 10 lb. It takes a fairly large bait.

The following are natives of the British seas: 1. Labrus auratus, Bloch, the Ballan Wrasse, inhabiting chiefly the eastern coast, but also found in the Pacific Ocean, 2. Labrus labrus, Don, the English wrasse, the colours of which vary somewhat, Jenyns, the Corkling, our smallest species, but only four inches in length; 3. Labrus niger, Gmelin, a large and not uncommon kind; 4. Labrus tricolor, Gmelin, a beautiful red fish, with the black spots on each side of its back; 7. Labrus auratus, Gmelin, observed by Pernan, and, since by Mr. Cochrane and somewhat doubtfully as a true species; 8. Labrus janny, one of the most beautiful and valuable of our fishes, which is called the Mediterranean, where it is common on muddy ground in seven fathoms water, living among seaweed; 9. Ctenolabrus reale, the Gilthead, a common and handsome species of wrasse found in the Mediterranean; 10. Ctenolabrus cornutus, which is possibly only a variety of 11. Ctenolabrus gilchristi, known only from the description of Pennant, who found it in Anglet; 12. Ctenolabrus sardus, first observed by British by Mr. Coupland; 13. Labrus anax, found in the Mediterranean, and 14. Ctenolabrus osilis of Lusitania, not uncommon species.

(See Marshall's British Fishes for figures of all these.)

WRAY, ROBERT BATEMAN, an engraver of gene.

was a son of the Rev. William Wray, vicar of Newporton in Wiltshire; and afterwards vicar of Brackenhill in the same county, where Robert Bateman Wray was born on the 20th of March, 1715, ...both on the father's and the
another's side he was allied to some of the best families in the country. He was fourth in descent from Sir William Wray of Grocesthorpe, in the county of Lincoln, Bart., who was created Lord-club to the duke of Northumberlaad for 2d. But in the branch of art were the labours of native artists very liberally rewarded in those times, except in some rare instances.

The following are the most remarkable of Mr. Wray's works, and they are here placed in the order in which their merit is supposed by some competent judges to rank:

1. Dying Cleopatra, in the Medici, Med. 2. Heaven's, a head, a copy from the engraving in the works of Soho Square, who had recently invented a method of copying antient engraved gems, was so much impressed with the merit of Mr. Wray's works of the same kind, that he engaged him to engrave some of those of his selection. Mr. Wray's name thus became extensively known, and his original productions were sought after with avidity even in Italy. At a subsequent period, when Henry, eighth Lord Arundel, visited Rome to collect works of art for the purpose of decorating his magnificent mansion of Wardour, he was surprised to hear of the fame of a man who was then residing within a few miles of his own gate in England; for in the year 1759, after a residence of more than thirty years in London, circumstances had induced Mr. Arundel to fix himself in Church Street, Salisbury. To an artist of the celebrity which he had now acquired, locality of abode was of little moment.

It was at Salisbury that he produced some of his best works, the base on which his reputation with posterity will chiefly depend. The difficulty of engraving figures on hard stones in the manner of the antient Greeks is shown by its rarity in modern times; and although it has been cultivated in Italy, it is not a common success, in England is scarce has had a rival. If some of the Italians have surpassed him in facility of execution, and in the number of their works, none have been his superiors in expressing the actions, and in female grace and beauty. That scope of his talents will be easily imagined, when it is stated that the head of the dying Cleopatra, which he esteemed the most perfect, was the most difficult of his works, was
Locality.—Europe; America.

Example, Troglodytes europaeus.

Locality.—Switzerland.

Generic Character.—Bill moderate, nearly straight; the culmen gently inclining towards the tip, which is rather; the gonys straight. Wings short, rounded; the first and secondary tail-feathers are rounded to the tips ovate, but, with the shaft, forming a fine soft point beyond the webs. Tailasus lengthened. Middle toe longest; lateral toe much shorter, and very unequal; the outer longest, and slightly connected to the middle; inner toe shortest, and clut to the base; hinder toe shorter than the tarsus. All the claws slightly curved. (Sw.)

Locality.—Brazil.

Example, Loemus squamata.

Tichadroma, Ill.

Generic Character.—Bill very long, slightly arched, cylindrical; the base angulated; the tip depressed. Notostrils naked. Feet long and slender. Exterior toe united to the base of the middle; hinder toe with the claw very long. Wings lengthened, broad; the first quill spurious, the second and third, graduated, the three next longest. Tail short, round, broad, and soft. (Sw.)

Locality.—Europe.

Example, Tichadroma muraria. [Creeper.]

Mr. Swainson arranges the Golden-crowned Wrens, or Golden-crowned Wren family, among the Sylviae, in the Prince of Canino and Musignano, in his Birds of Europe and North America, places the genus Troglodytes, of which he records one European and three American species, next to the genus Certhia, in his subfamily Certhinae; and he makes Regulus, of which he notices three European and three American species, the first genus of his subfamily Parvin. Regulus, in the Prince's arrangement, is immediately followed by Parusus.

The Troglodytinae of Mr. G. R. Gray form the seventh and last subfamily of his family Certhidae, and comprises the following genera:

We proceed to illustrate this group by examples of the genera Troglodytes and Regulus.

Troglodytes.

Example, Troglodytes europaeus, Motacilla troglodytes, Linn.

Description.—Male.—Upper parts brown, marked with very narrow transverse stripes, which are disposed on the top of the back; quills marked externally with alternate large and small spots; tail coverts and feathers striped transversely with black; above the eyes a narrow white band; throat and breast greyish buff or white; all the posterior parts brown, marked with white spots and black transverse stripes. Total length within four inches.

Female rather less than the male, with the tints more rusty and the transverse stripes less strongly marked.

This is the Troglodyte, Roylelet, Buef du Dieu, Berichot, and Roy Bertrand of the French; Riedl, Regillo, Rosino, Ipsen, Ienti, Ercolano, R. d'acelli, and Suez-contratte of the Italians; Nelle Konig of Brunnich; Schrenking, Koniker, and Zurchucher of Kramer; Zaun Sanger of Meyer; Haus and Waldaukunigs of Bremh; Vreen, Vran or Ban, Cutty, Katy or Kitty Wren, and others of the British; Drees of the ancient British.

Habits.—This familiar little bird, which has become sacred, like the robin, from the confidence which it shows in courting the neighbourhood of man, creeps about the hedges, making small flights, and in its search for insects generally entering the lower part of the hedge and working upwards. Like the robin, it will sing close to the hedges in mid winter, but the frost and snow are sometimes too much for it, and the little creature perishes with cold, which however it avoids by roosting in warm cattle-sheds, for the sake of the animal heat of the inmates, and in other sheltered places.

The nest is placed variously, according to circumstances.

Linnæus says "significant sub termum," and it has been sometimes found in a bank or old road. The material generally varies with the situation. Thus if the nest be built against the side of a hayrick, hay is used; if against the trunk of a moss-grown tree, that moss is employed. It is large in proportion to the bird, and the shape is generally oval, the top being in the form of a dome and the entrance by a small hole at the side or sometimes at one end. Feathers generally form the lining. Seven, ten, and ten more eggs, white, with a few pale red spots, but sometimes spotless, are here deposited, and about ten days suffice for hatching the brood, sixteen of which is ascertained has been seen in one nest, a large family for the winter, parents to rear. But they are most anxious in collecting food for their young, and when the incubation is at the female sits very close, depending for her sustenance upon the male, who, in constant attendance, feeds insects and worms are their food.

The feathers in a wren's tail make a killing sound in the early part of the season.

In the Portraits d'Oiseaux (1807), the following quaint appears under the cut of this species:

* "Del oiselet, qu'on nomme Royellet, On retrouve l'agile à debat et quyrole. Toujours est plus, tant mache cue bصندل; Et toujours est de, aimant eure senter."

The first lines allude to the old fable of the cock which was supposed to exist between the wren tail and eagle.

The Wren.

Regulus.

Example, Regulus cristatus, Motacilla Regulus, Linn.

Description.—Old Male.—Upper parts of the body of an olive hue, slightly tinged with yellowish; two transverse bands on the wings; faintness on the top of the head long, rather loose, of a bright orange yellow, approaching to a golden colour; on each side of the head a single black band extending to the occiput; face is the base of the bill, region of the eyes, sides of the head, and lower parts ash-coloured, slightly shaded with grey; quills and tail-feathers grey-brown, bordered externally with a colour inclining to olive and internally with whitish; iris deep brown; bill black; feet blackish. Total length about three inches and a half.

In the Female the crest, instead of being orange, that of the male, is of a linen colour; the black band which bars the lateral jaw is less wide, and all the shades of the plumage are less vivid.

In the Young the whole plumage of the crest are grey, approaching to olive; it is only after the first month that the sexes are distinguishable.

Varieties.—Top of the head aureo-blue; a less

Digitized by Google
variety has the head and part of the plumage white; but another has the crest of azinotellum, and plumage is more like that of a.

**Geographical Distribution.**—M. Teminick states that this species is sufficiently common in all the countries of Europe up to the Arctic Circle. It is an inhabitant of Russian, Siberia, Sweden, Norway, and Denmark, but from the northern soil. This appears to be a kind of migration to the more temperate parts down to the Mediterranean. It is fairly spread over England, Wales, Scotland, and Ireland, and is found in Orkney and Shetland. It has been received from Siberia, Edwards and Van Reitnagel, and the material of his description has been seen in Japan.

This species is the Rottlet and Rottlet rumpus of the French, and Pennant thinks, with reason in our opinion, that it is the sithe a Sante or Sante of Belon; it is the "Gape rejo de ducelli" of the Italians; "Kongefyl" of the Swedes; "Fugle-Konge" of Brunnich; "Pengelgen" of Walter; Gehörner Sanger, Sommer Zaunkeiln, Nordisches Aufsammungs- und Geographische Verzeichniss, etc.

**Habits, Food, &c.**—This beautiful and active little bird, which I have, so far as I know, never seen in Great Britain, may be looked upon as a very common and frequent visitor among the branches, especially of some fach or fir, running actively along and clearing away the insects. It is far from uncommon round London; and if the observer approach cautiously and stand still, he may watch its motions within a very few feet without disturbing it.

Pennant says that he saw this bird suspended in the air for a considerable time over a bush in flower, singing very melodiously, but with a very weak note, not differing much from that of the Wren, and that the only difference was that a Golden-crowned Wren, which had lost its mate and never found another, continued to sing from May to the end of August. On the contrary, another of the same species, that I possess in my possession, of a fir tree, was heard, never ceasing its notes as soon as the young were hatched. This little family gave Montagu the opportunity of writing one of his most interesting descriptions of the habits of birds:

When first I discovered the nest, I thought it a favourable opportunity to come in and study the interior, and the bird feeding in the next window, and after they became familiar with that situation, the basket was placed within the window, then at the opposite side of the room. It is remarkable that, although the female seemed regardless of danger from her affection for her young, yet the male was as active near the nest as ever. He was placed within the room, and yet would constantly feed them while they remained at the outside of the window; on the contrary, the female would feed them at the table at which I sat, and even while I held the nest in my hand, provided I remained motionless. But on moving any hand over the nest, while she was on the edge of the nest, which I held in my hand, she made a precipitate retreat, mistook the open part of the window, knocked herself against the glass, and lay breathless on the floor for some time. However, recovering little, she made her escape; and in about an hour after I was agreeably surprised by her return, and she would afterwards frequently feed the young while I held the nest in my hand. The male bird constantly attempted to fly from the window, but was always driven back by the female. I continued to watch this bird for some time, and it was afterwards frequently fed, and the nest soon disappeared. The female was very frequently repeated in the space of a minute or a half hour, or, on an average, sixty-three times in an hour; and this continued to last for some time. After the eggs were laid, each young one, each would receive seventy-two feeds in the day; the whole amounting to more than five hundred and seventy-six. From examination of the food, which, by accident, now and then dropped into the nest, I judged from those weighed that each feed was a quarter of a grain upon a medium; so that each young one was supplied with eighteen grains' weight in a day, and as the young birds weighed about seventeen grains at the time they began to perch, they consumed nearly their weight of food in four days at that time. I could always perceive, by the animation of the young perch, when the old one was coming—probably some low note indicated her approach; and, in an instant, every mouth was open to receive the insect morsel. But there appeared no regularity in the supply given by the parent bird; sometimes the same was fed two or three times successively; and I generally observed that the strongest got most, being able to reach furthest, the old one delivering it to the mouth nearest to her; and after each feed she waited a while to see if any mated.

Mr. Yarrell remarks that the nest is placed under a branch of fir, and generally towards the end of the bough being supported by two or three of the laterally diverging and pendent twigs, which are interwoven with the moss of which the outside of the nest is principally composed. This accords with our own general observations; but we have seen the nest, with young in it, in a tall yew hedge. Its most frequent lining consists of feathers. The eggs are pale reddish white.

The out of the 'Santee, of the 'Portraits d'Oyeaux, the 'Rwren, of the 'Rrowsers, the 'P.Article, of the 'Regulus, and of the 'Regulus, are also to be seen in Britain. M. M. T. W. W. Wren, Matthew, Bishop of Ely, was the eldest son of Francis Wren, a merchant in London, where he was born, in the parish of St. Peter's Church, on the 3rd December, 1625. He was admitted of Pembroke Hall, Cambridge, on the 30th June, 1643, and was elected fellow on 8th March, 1644, and took his degree of M.A. on 22d July, 1648. He entered into holy orders in 1610. In 1610 he was presented with the rectory of Teversham in Cambridgeshire. In 1621 he was appointed chaplain to Prince Charles. He attended the prince in his "strange journey into Spain" in 1629, and having thus had opportunities possessed by scarcely any other churchman of ascertaining the opinions and feelings of him who was afterwards to be king, he acquired an influence with the clergy, which made him aware of the main causes of the calamities which soon afterwards
in 1629 he was made dean of Windsor and Wolverhampton, and in 1629 one of the judges of the Mar-1 Chamber. He attended Charles I. on his visit to Scotland in 1633, but failed to sound the religious feelings of the country so candidly as he always and did those of his royal master. In the following year he was made bishop of Hereford, and translated on 5th December, 1630, to Norwich, and on 5th May, 1638, to Ely. He was employed in the construction of the Scottish House of Lords, and in the reading of the Baptist Church at Eding. 1637 occasioned those riots which were followed by the submission of the Covenant, and finally led to the great civil war. On the 19th December, 1640, Hampden was sent by the Commons on a message to the Lords to accept the measures proposed for the improvement of the laws. At the "high nature" against Wren, "concerning the setting up of idolatry and superstition in divers places, and exercising some acts of it in his own person, with divers other matters of great importance, and that they have information likewise that he endeavours an escape." An answer was returned, that he had been ordered to find bail in 10,000l. to attend the judgment of parliament. According to a paper preserved in the "Parentalia" of his nephew, the number of persons against him related to such charges as the raising of the altar, kneeling at the sacrament, and other matters of ceremony, which afterwards became part of the uniform observance of the church of England. There is no doubt however, that the real ground of the charge against him was the despotism of his own views in clerical matters, for Clarendon, who praises his learning, says he was a man of severe sour nature, and charges him with having so vexatiously enforced the discipline of the church of England, public and private, on persons of the clergy, and others, as to drive many of them from his diocese. The articles of impeachment were not pursued, but he remained a prisoner in the Tower till the restoration of 1660, when he was released in his see. He framed the forms of government of the 20th of May, 1660, the year of the Restoration. He died on the 24th April, 1667. He built the chapel at Pembroke Hall, Cambridge, of which his nephew Sir Christopher Wren was the architect. Of a few controversial pamphlets which he left behind him, the titles will be found at length in the "Bibliography Britannica."

WRKN, MATTHEW, eldest son of Bishop Wren, was born at Cambridge, in 1629. He was for some time a member of parliament. He is also secret to the bishop of Clarendon, and afterwards to the duke of York. He died in 1672. Matthew Wren was the author of "Considerations on Mr. Harrington's Commonwealth of Oceana, restrained to the first part of the Preliminary; London, 1658."

WRKN, SIR CHRISTOPHER, born at East Knoyle, Wilts, October 30th, 1632, was of good family, being the son of Dr. Christopher Wren, chaplain in ordinary to Charles I., and dean of Windsor, and nephew to Dr. Thew Wren, successively bishop of Hereford, Norwich, and Nly; and from the former of these he seems to have inherited a taste for scientific and literary studies, that of his brother and nephew for the State of the Monarchical and Popular Government; in the "Vindication of the Considerations upon Mr. Harrington's Oceana; Oxford, 1689. 8vo.; London, 1890. 8vo.; On the Origin and Progress of the Revolutions in England," in Gutch's "Collected Oration, vol. i., 1791."

WRKN, SIR CHRISTOPHER, born at East Knoyle, Wilts, October 30th, 1632, was of good family, being the son of Dr. Christopher Wren, chaplain in ordinary to Charles I., and dean of Windsor, and nephew to Dr. Thew Wren, successively bishop of Hereford, Norwich, and Nly; and from the former of these he seems to have inherited a taste for scientific and literary studies, that of his brother and nephew for the State of the Monarchical and Popular Government; in the "Vindication of the Considerations upon Mr. Harrington's Oceana; Oxford, 1689. 8vo.; London, 1890. 8vo.; On the Origin and Progress of the Revolutions in England," in Gutch's "Collected Oration, vol. i., 1791."

Yet so far this was mere fancy being adopted, that it was last sight of all together in rebuilding the city: the new streets rose up in their space and intricate maze of narrow lanes which are now but also the road that has been improved: so, of all, instead of the line of streets seen along the Thames, which Wren proposed, the river is entirely shut out from view by wharfs and walls, now in much space as to other scheme for improving the banks. It is not indeed to be wondered at that much such a scene of confusion, and under the pressure of a necessitate, that nothing should have been more to the mind of that they did not inconvenience, still it is to be wished for commodiousness in the first instance, and for embellishment to grow up
The composition is compact and simple, forming a single general octagonal mass, surmounted by a cupola, and extended on its west side by a portico, and a short nave or vestibule within; and there is also a great deal of play produced by the alternate curved sides of the main body. Of this design one great recommendation insisted upon by Wren was that there would be only a single order; yet though this is true as regards avoiding superelevation or order over order, there would in fact have been two orders (both Corinthian), the larger one for the portico or vestibule, and one upon a smaller scale (but raised to the same level of entablature, by being placed on a lofty stylobate) in the side elevations, which would have been surmounted only by an attic and balustrade. Such a combination of two minories might perhaps have been objected to by some as rather licentious, notwithstanding that there is ample authority for it in the works of Palladio and others of the Italian school; but it would at all events have produced picturesque variety, and the larger order of the portico would have been impeding by contrast with the other. It is further to be observed that that ordinance is kept distinct from the other by being confined to a separate elevation of the building. As to the interior, the parts are beautifully grouped together, so as to produce at once both a regularity and nicety, yet it does not seem by any means particularly well adapted for the Protestant service, there being no space for a collected congregation, except in the circular area beneath the dome, which could not be fitted up for such purpose without being further included; whereas also in other respects the grandeur of the ensemble, as it shows itself in the plan, would have been greatly impaired.

The composition of that first idea with the one afterwards adopted makes evident almost opposite modes of treatment both as to arrangement and proportions. While the first exhibits concentration and uniform spaciousness, the other is more extended as to length, but contracted in other respects, and the diagonal vistas that would have been obtained in the other case are altogether lost. It may be observed too that the nave, or western arm of the cross, is rendered apparently shorter than the eastern one, externally, being broken so as to form a second or western transept.

The first stone of the present edifice was laid June 21, 1673; the choir was opened for divine service in December, 1677, and the whole was completed in thirty-five years, the last stone on the summit of the lantern being laid by the architect's son Christopher in 1710. Taken altogether, the present St. Paul's is a truly glorious work—its cupola matchless in beauty; yet all noble as it is, the fabric will not bear to be rigidly scrutinized in the spirit of capricious criticism; and of late years no little of such criticism has been brought to bear against it. Among other faults, it is alleged that its real form and construction are masked, the upper order of the side elevations being merely a screen concealing the buttresses and clerestory windows of the nave; also that the same is in a great measure the case with the cupola, the external dome being considerably lovelier than the inner one, being so elevated chiefly for effect—True; and that effect is most admirably accomplished. The last reproach is all the more insidious, because it has, if not proceeded from, been repeated by those who, while they constrain St. Paul's dome as being larger than the interior actually required, not only tolerate but are in ecstasy with a Gothic spire—a feature built altogether for external effect, and quite useless as regards the interior of the structure, otherwise than as giving stability to the tower. Another charge which has now started up against Wren is that he was either ignorant or grossly
Wren was possessed of the office of surveyor-general (which he had held for forty-nine years), very little to the credit of George I., and to the disgrace of one of the most fortunate men who has ever succeeded him in that capacity has preserved a name from oblivion by perpetuating it for lasting shame and contempt. To Wren himself however the discharge from office must have been rather a wholesome release, and, verging towards old age, he could then have little further worldly ambition, even had he already amply gratified it. The close of his life was so much to be pitied as to be envied, for if he passed the last five years of his existence in retirement and in comparative poverty, there is yet no one of the unnumbered host of minié placid content. The struggles of dissolution were sent him, for without any previous symptoms of approaching death he was found dead, reposing in his chair after one (Fitch's) of his last recorded acts of architecture. He received the tardy honour of a splendid funeral at St. Paul's, where his remains were deposited in the Crypt, with no other adornment to his tomb than the inscription on it, with the sublime eloquence of genius:

"A Monument for Wren."

Christopher, the architect's son by his first marriage, and who sat in parliament for Windsor about 1706—author of a work entitled "Numismata Antiqua," 4to, 1708; and he composed the chief part of the "History of the Royal Family," 2 vols., 1709—died February 12, 1743. A memorial tablet was erected in the church of Windsor, in the fifty-first year of his age.

Chronological List.

1663 Pembroke College Chapel, Cambridge.
1664-9 Sheldonian Theatre, Oxford.
1664 Buildings at Trinity College, Cambridge.
1665-6 Temple Bar.
1667 Royal Exchange, London.
1668-77 Emmanuel College Chapel, Cambri.
1668 Custom-house, London.
1670 Temple Bar.
1671 Temple Church, London (202 feet high).
1670-4 St. Sepulchre's, Newgate.
1671-7 St. Mary-le-Bow.
1671-86 St. Lawrence, Jewry.
1672 St. Stephen's, Walbrook.
1672 St. Paul's, London.
1672 St. Mary-at-Hill.
1673 St. Benet Fink, Threadneedle Street, now taken down.
1674-4 College of Physicians, Warwick Lane (converted into market).
1675 St. Paul's begun.
1675 Royal Observatory, Greenwich.
1680 St. Bride's, Fleet Street.
1680 St. Swithin's, London.
1681-2 Gateway Tower, Christ Church, Oxford.
1682-90 Chelsea Hospital.
1682 St. Anthonie's, Watling Street.
1683 The Palace at Winchester, which was left unfinished, and now converted into a house of Wine.
1683 Queen's College Chapel, Oxford.
1683 St. James's, Westminster.
1683-5 St. Clement's, Eastcheap.
WRESTLING affords so obvious a means of trying the bodily strength and activity of men, that it has probably formed one of the athletic exercises of almost every nation, at least of every warlike nation. It was in use among the Greeks from the earliest times. Perhaps the oldest description of a wrestling-match is that given in Homer in the ' Iliad' (xxxi., 700, &c.). This contest was one of the great games which Achilles provided to dignify the funeral of his friend Patroclus. The wrestlers were Ajax and Antilochus, at St. Edmund's, London ('for the victor was a tripod, valued at twelve oxen; the compensation to the vanquished for his toil was a female slave, valued at four oxen. The wrestlers were naked, except a girdle round the loins. Having walked into the centre of the ring, they laid hold of each other's arms and strong hands; and their efforts to throw each other down were such, that, as Homer describes it, their backs creaked, the perspiration flowed from them, and many jolts, red with blood, they exchanged. It seems that the actual struggle was continued so long that the spectators became weary, and Ajax then proposed to Ulysses that the one should try to lift the other. Ajax immediately lifted Ulysses, who, with his usual skill, struck his bullying opponent with his first blow, and sent him down on his head. The porter of Ajax, thrown off his balance, fell on his back, with Ulysses on his breast. If it had been the Cumberland game, Ulysses would have been declared the victor, but the Greek contest, which was a terrible trial of strength and not at all a sport, the power of the body being then brought into action to obtain the most advantageous grasp of each other, and displaying in their preparatory movements, as well as in the subsequent struggle, a series of beautiful attitudes. They are represented on ancient monuments in every variety of position, sometimes grasping each other by the wrists, sometimes round the shoulders, and sometimes the one has seized the other round the loins, and has lifted him up with his head downwards. This mode of wrestling was not purchased; women were not permitted to wrestle; but there was another kind, which was indeed occasionally the concluding part of the erect wrestle, called ἀνάκολονάθες, in which they struggled on the ground; this was always a cruel contest, sometimes accompanied with biting and similar maltreatment. When one of the combatants yielded, or was quite exhausted, or actually strangled.

The πίλαγχος (wrestling) was also combined with the πηγή (boxing), and this alternate game was called πηγαδιστέων (πήγας, 'all' or 'every,' and ἐπιθέω, 'force' or 'strength'); every blow given to each other's limbs was considered a point. The five principal exercises of the Greeks were also combined into one game, which was called πηγαδομα: in this game all the exercises were performed by the same persons in the same day; and the five exercises were (1) leaping (ἀναπηγα), throwing the discus (ἰππασσεμέν), throwing the spear (δισφόνος), and wrestling (πίλαγχος).

The Roman wrestling was an imitation of the later forms of Greek wrestling, without any points of difference deserving of notice.

'Merry England,' of the old time abounded in bodily exercises of many kinds, and wrestling was one among them which was practised in all parts of the country. Except in the north, the game seems to have been generally similar to the Cornish game as still in use. In the common game, the hold was taken by the collar and waistbands in the Priam game, the Phoebus, or one hand on the waist, and each had a girdle, something like aawl, one shoulder and under the other, for his opponent to take hold of. A ram was one of the most common prizes. In this Prologue to Chaucer's 'Canterbury Tales,' we are told of the Miller that

As wrestling he would have away the ram.'

But, according to the old poet called 'A Lytel Geste of Robyn Hode,' prizes of greater value and dignity were sometimes given—a white bull, a great coursier, with saddle and bridle, a pipe of wine, and a red gold ring.

In old times the Londoners were distinguished for their skill in wrestling. Matthew Paris, in 'Hist. Ang,' anno 1222, says that they held their anniversary meeting for this game, in the 6th year of Henry III., near the hospital of Westminster, and the place was met by the inhabitants of the city of Westminster and suburbs. The prize was a ram, and the Londoners, having been victorious, accepted a challenge to meet their opponents in Westminster; they did meet them, and the result was a quarrel, a fight; and the monument of Stow mentions another tumult at a wrestling-match near Clerkenwell in 1433. Wrestling had fallen much into disuse in Stow's time. 'In the month of August,' says Bartholomew the apostle, 'before the Lord Mayor, aldermen, and citizens, placed in a large tent near unto Clerkenwell, of old time were divers days spent in the pastime of wrestling, where the officers of the city, namely, the sheriffs, serjeants, and the king's bench, and weigh-house (now so many men), and others of the city, were challengeers of all men in the suburbs, to wrestle for games appointed; and on other days before the Lord Mayor, aldermen, and sheriffs, in Penfurbie Field, to shoot the standard, broad arrow, and flint, for gammon; but now, of late years, the wrestling is only practised at Bartholomew's day in the afternoon, and the shooting, some three or four days after, in one afternoon, and no more.'

Wrestling is not much practised in England at the present time, except in the north, especially in Cumberland and Westmorland, and the south-west, in Cornwall and Devonshire. The Cornwall and Cumberland wrestling are distinct games, and are performed in quite a different manner.

In a Cornwall prize-game the wrestlers wear a strong jacket, which seems to have superseded the old girdle round the shoulders, and is used for the same purpose. They generally take hold, not deliberately but by a catch, mostly aiming to seize the jacket with one hand as far as possible behind the shoulder, while with the other hand they endeavour to grasp the sleeve of the opposite arm about the wrist or elbow. The shoulder-hold is mostly retained, if possible, but the other is shifted when in the course of the struggle the opportunity presents itself of passing the arm round the loins, so as to give what is called a Cornish hug, or in any other way which offers an advantage. A powerful wrestler, when he gets an extra hold, sometimes pull his opponent, head foremost, and heels up, over his shoulder. The most objectionable part of the Cornish game, as sometimes practised in London, though, we believe, it is not common in Cornwall or Devonshire, is that of wearing heavy shoes, and kicking each other's elbows in; though the front of the leg is defended by a strong piece of leather, the blood is made to flow abundantly. Those who wish for a more detailed account of the Cornish wrestling may consult 'Partenopara: the Inn-Play, or Cornish-Hug, a Hudsonian method which comprehends the passes, and brake all Holds, and throw most Falls mathematically;' by Sir Thomas Parkyns, of Bunny, Barretom, 'Nottingham, 1717, 2nd ed., 10o. Prefixed are 'Institutes for Young Wrestlers, by William Tomastall.'

The Cumberland wrestling is essentially distinguished from that of Cornwall by the manner of taking hold and by the settled rules of the game. In a prize game the
WR I 588 WR I

wrestlers advance into the centre of the ring, shake hands, throw off coat, waistcoat, and shoes, and then proceed to take hold, which is done by each passing the left arm over the right shoulder of his opponent, the right arm under the left arm, and grasping the wrist behind the back. In doing this there is an obvious advantage in taking hold as low as possible on the back. If one of them has got such an unfair advantage, by a 'snap,' or sudden catch, the other immediately unlooses his hands, and the hold must be taken anew; nor does the wrestling commence till each is satisfied that the hold of his opponent is not likely to be broken. The wrestlers put in practice some of the numerous feats and trips of which every first-rate wrestler has some almost peculiar to himself. The wrestling is on the green sod, and is, for the most part, perfectly harmless, and seldom of long duration, though the struggle is exceedingly severe while it lasts. If one throws the other on his back, he is the winner, whether he stands or is pulled down by the loser upon himself. He who is thrown is technically said to be 'grassed.' If they come to the ground side by side, the fall is not fair, since they are over against each other; passing into succession till all have wrestled once, when the winners wrestle again, and the losers retire till only a single pair remain, who are generally the most powerful and skilful of all, and then the fast and most skilful man is the winner; he who is in possession of the first prize. A great many Cumberland wrestling-match brings together nearly all the best wrestlers from every part of Cumberland and from many parts of Westmoreland. The largest and most powerful men enter the ring; for all weights, the smaller and lighter men wrestle in the ring for weight, for whom separate prizes are assigned. A wrestler who intends to contend for the chief prizes puts himself through a course of training for weeks previously, as if he were preparing for a long battle. Till his mind is so thoroughly prepared, wrestling is practised, with little variation, throughout the lowlands of Scotland, as well as in Northumberland and Durham.

The other favourite games of the Cumberland and Westmoreland men are leaping and running: these two games generally accompany the wrestling as prize games, in which the best wrestlers frequently contend, as well as others. In running perhaps the inhabitants of other parts of England may equal them; but in leaping—high leap, standing-jump, running-jump, and hop-step-and-jump—they are probably unrivalled.

A prize-game of Cumberland wrestling is held every year in London: many of the wrestlers are life-guardians. Frequently spirits are given them. Broth is a native wrestling, very fine, and very skilful. It is also held in London and Westminster. (Dictionary of Greek and Roman Antiquities; Potter's Grecian Antiquities; Strutt's Sports and Pastimes, by Horse; Stowe's Survey of London.)

WRIGHT, EDWARD, a mathematician, the account of whose life and writings is generally so loosely given that it will be worth while to devote a little more space to him than his celebrity would otherwise demand. He was born at Garveston in Norfolk, but the date is not known. He was educated at Caius College, Cambridge, of which he became a fellow. Dr. Hutton (in the preface to his logarithms) quotes a translation of what he calls 'a Latin piece taken out of the annals of Caius College, Cambridge,' in which it is said that Wright was 'learned in knowledge, and was most expert in the making of instruments: that he was the first inventor of the plan of bringing water from Ware to London (in what is now called the New River), but that he was prevented by trickery from bringing it into actual execution. It is also related by Burne, who gives some account of him in the list at the end of the translation of Manlius, that Wright was mathematical tutor to Prince Henry, son of James I, and that he was the first prince he caused to be made in Germany a sphere which had not been made before, as if the moment of the system, but would suffice to foretell eclipses for 17,000 years. This sphere was damaged in the civil troubles, but was recovered and repaired by Sir Jonas Moore in 1640, and is still preserved at Caius College, Cambridge.) 1673, says that it was then at Sir Jonas Moore's official residence in the Tower. But Wright's fame rests entirely upon his discovery of the mode of constructing the sea-chart which is now in universal use under the name of Mercator's Projection. When sea-charts were first made, the degrees of latitude were made of equal length; in fact the chart was nothing more than a map in which degrees of latitude and longitude were represented by rectangular parts throughout. In such a chart attempts were made to navigate by following the course marked out by a line on the map joining the port of departure with that of destination, and the error was considerable. Mercator (Mercator, Gerhard) as early as 1569 first ventured the idea that degrees of latitude ought to increase in length; and this was afterwards found out. Mercator accordingly constructed rough charts probably by transferring ruler lines from the globe to the chart, making them straight in the latter, in which the degrees of latitude increase, and in such a table the proper and the: but there is no sufficient reason to suppose that he had the least idea of doing more than that or that he had investigated the mathematical problem of laying down the sphere on a plane as that the ruler lines should be straightened. But it is absurd, in the worst sense of the word, to expect writers to originate or to cite ideas from Wright, since the maps of the former were published perhaps before the birth of the latter, certainly thirty years before he published anything on navigation. And for this single reason it is not, perhaps, as might have been expected, 'By occasion of these maps of Mercator, I first thought of correcting so many and such gross errors, &c.' All that could have been learned by Mercator's hint, Wright did learn: it must first be shown that he had the idea before it can be suspected that the latter copied it.

To instruct himself in practical navigation, Wright went to sea in 1658, on a voyage to the Azores, with George Earl of Cumberland, a dispensation from residence in England having been given him on this occasion. He had not been long flourishing in Britain: a few years before Wright, many captains mocked them that read charts or cross-staves, saying they cared not for the sheep-skinnes, they could keep a better account of the wind and weather. Then them that observed sun-shines for finding the latitude, they would call sun-shooters and star-shooters and ask if they had hit it. In this voyage Wright made many observations, and perhaps thought of his method of drawing the chart. Nothing of this however was published until 1654, when Blundell, in the second edition of his 'Exercises,' gave the mode of constructing the chart and the following account of it: 'Mercator hath, in his universal card or map, made the spaces of the parallels of latitude in a straight line as also held in London. If one should be made to go north or south, the former part would be a straight line and the latter part a series of curves. This would require a very accurate chart. If he had the power of the large share of credit. He had a full and geometrical power over his subject; nought but the differential calculus could have given him his power. He knew well that the infinitely small increments of the latitude and the longitude, and the corresponding parts of the chart, are in small circles and squares. He knew that one of the charts was the meridian circle, and thence formed his celebrated table by the sums of the meridians, expressing that it would be made more exact the
smaller the interval of the angles of those sects is made.

Had those who have written about him studied his work, the 'geometrical conceit' which he gives for dividing the meridian would have become a common and well-known illustration, and would have appeared in collections of examples, as in Dr. Guettard's translation of his Rationale, which is not completely as there was nothing empirical about his table. 'Let the meridian route upon a straight line beginning at the equinoctial, the globe swelling in the meantime in such sort that the semidiameter thereof may be represented by several other beautiful and perspicuous tables. The angle between the equinoctial and semidiameter intersecting at night angles upon the foresaid straight line: The degrees, minutes, seconds, &c. of the meridian, in the straight line, as they come to touch the same, are the divisions of the meridian. The effect of dividing the meridian of the nautical planisphere may satisfy the curious exactness of the Geometrician; but for mechanical use, the table before mentioned (which seems to follow) may suffice.' The result of the integral calculus, namely, that the sums of the sectants in Wright's table are ultimately proportional to the logarithmic cotangents of the semi-complements of the latitudes, was first announced by Henry Bond in Norwood's 'Epistola de magnis aequilibus descriptis,' 1651; and a more extended elaboration of the subject appeared in Gunter, 1665. It was first demonstrated by James Gregory, in his 'Exercitationes Geometricae,' 1668, and afterwards by Halley. (Phil. Trans., 1695; see also the 'Miscellanea Curiosa.')

On the invention of logarithms became public, Wright immediately applied himself to the study of the new method, and translated Napier's description of his canon. This translation was forwarded to Napier at Edinburgh, received his approbation and a few lines of addition, and was published in 1616 by the son, Samuel Wright, also of Calus College, with a preface. The migration of the books from England, and, for some time, the lack of the scholar a nation of 50,000, in philosophical transactions, and to the transactions of the Linnean Society. This genus was formed by Robert Brown, and has been divided into two, a salver-shaped corolla with the throat crowned by ten divided scales; the stamens extended, attached to the throat of the corolla, and the anthers sagittal, cohering by their middle to the stigma; the ovaries two, cohering; the style single, filiform, dilated at the top; scales five in the corolla. The petals have the calyx outside the corolla; the follicles distinct or combined with adnate placenta. All the species erect shrubs or small trees, with opposite leaves, and corollas of mostly white flowers. The petals have no stamens, the corolla is a little more than half the length of the throat, and the tubes of the corolla six times longer than the calyx. This plant is a native of Ceylon, and has sweet-scented flowers with a form resembling those of the Jasmine. The wood is white, of a fine grain, and susceptible of polish, and is used by the cabinet-maker. The bark of this shrub, which goes by the name of Compos, bark in Great Britain, and Palapatta in India, is asserted to be a specific in dysentery and of use in most disorders of the bowels. Its milky juice is also used as a vermifuge.

W. antisydenticus has obovate, oblong, acuminate, glabrous leaves, nearly terminal corollas, the follicles distinct, and the tube of the corolla six times longer than the calyx. This plant is a native of Ceylon, and has sweet-scented flowers with a form resembling those of the Jasmine. The wood is white, of a fine grain, and susceptible of polish, and is used by the cabinet-maker. The bark of this shrub, which goes by the name of Compos, bark in Great Britain, and Palapatta in India, is asserted to be a specific in dysentery and of use in most disorders of the bowels. Its milky juice is also used as a vermifuge.

W. cocinea, Scarlet Wrightia, has almost sessile ovoid-oblong leaves; the flowers three or four together, terminal; the corona in the throat 6-lobed; the lobes crenulated; the follicles distinct and rough; the tube of the corolla 6 times longer than the calyx. It has large flowers of a dull red colour with a scarlet corona. It is a large tree, and its wood is remarkably light and firm, and much used by turners, and also for making palankeens. It is also useful in making handsome exhalations; small terminal corollas; the tube of the corolla longer than the calyx; the corona fleshy, inclosed in obtuse segments, the follicles scarous and distinct. This plant is a tree, and is a native of the Ceylons.
wounded a yellow juice flows from this plant, which mixed
with water will dye clothes dipped into it of a yellow
colour. \textit{W. tinctoria}, as its name indicates, is used for
the purpose of dyeing of a blue colour, and is employed as a
substitute for indigo.

The \textit{Nerium pascidium} of Roxburgh is placed by Don
in the genus Wrightia. It has oblong acuminated shining
leaves; terminal bracteated pedicels shorter than the
leaves; the tube of the corolla longer than the calyx; the
corona of five bifid villous segments; the follicles swollen,
oblung, obtuse. The seeds of this plant are furnished with
broad membranous edges. It is a native of Silhet, where it
is in common cultivation. The bark is distinguished by
anod of a woody fibre, which, being easily separable, is used by
the natives as a substitute for hemp, and is cultivated for
this purpose. Dr. Roxburgh found, on steeping the roots
in a fish-pond for the purpose of more easily separating the
fibres of the bark, that many of the fish were killed. From
this circumstance he gave it its specific name.

There are other species of Wrightia, most of which pos-
sess properties resembling those described, and, with the
exception of \textit{W. indigotica}, which is a native of New
Holland and Java, they are all natives of the East Indies.

(Don's Miller; Lindley, \textit{Natural System}.)

WRINGTON. [SOMERSETSHIRE.]

WROTHLESLEY, THOMAS, the fourth earl of South-
ampton, was the son of the earl of Southampton who
was engaged in Lord Essex's conspiracy in the reign of
Elizabeth, and the great-grandson of the first earl of
Southampton, Henry VIII.'s lord chancellor, was one of
the most distinguished as well as zealous and constant
supporters of his party after Charles I., after the breaking
out of the civil war, until that king's death, and having transferred
his devotion to the son, and rendered important services
to Charles II. while in exile, was after the Restoration ap-
pointed lord high treasurer, and was, next to Lord South-
ampton, one of the chief stay of the restored government until his
death in 1667.

Lord Southampton, as a member of the House of Peers, was an
early member of the first proceedings of the Long Parliament,
and during its sitting in 1640 was accused of being a
royalist; but left the popular party, as did his friend through
life, Lord Clarendon, at that time Mr. Hyde, in the course of
the proceedings for attainting Lord Strafford. The
connection between the father of Lord Southampton and the
father of Lord Essex, the parliamentary commander-in-
chief at the commencement of the civil war, has led Lord
Clarendon to trace, in his eloquent sketch of Lord South-
ampton's career and character, the early agreement and
subsequent separation between the sons. 'The great
friendship between his father's houses made many believe
that there was a confidence between the earl of
Essex and his; which was true to that degree as could be
between men of so different natures and understandings.
And, in truth, if his boylike policy in the year 1642, when
they appeared both unsatisfied with the prudence and
politics of the court, and were not reserved in declaring it,
when the great officers were called in question for great
transgressions in their several administrations.' And then
after speaking of Lord Southampton's opposition to the bill
of attainder against Lord Strafford, he proceeds— From
this time he and the earl of Essex were perfectly divided and
separated, and seldom afterwards convened in the same
opinion; but as he worthy and bravely stood in the grasp
of the influence of the Straffords in life, so he did afterwards oppose all those invasions, which
were every day made by the House of Commons upon the
rights of the crown or the privileges of the peers, which
the lords were willing to sacrifice to the useful humour of the
other. \cite[II. iii. 228.]} When the king and parliament
took up arms against another, Lord Southampton zealously joined the king, by whom he was made a
member of his privy council and a gentleman of his bedchamber.
He was one of the king's commissioners to treat for peace
at Uxbridge, in 1645; and Lord Clarendon gives the fol-
lowing account of the zeal which he showed on this occa-
sion:— He was naturally lazy, and indulged overmuch
himself; yet as no man had a quicker apprehen-
sion or severer judgment in these kinds, since
then he had a hopeful prospect, no man could keep his mind
longer bent, and take more pains in it. In the treaty at
Uxbridge, which was a continued fatigue of twenty days,
he never slept four hours in a night, who had never used to
allow himself less than ten, and at the end of the
year was much more vigorous than in the beginning, who
made the chancellor to tell the king when they returned
from Oxford, that if he would have the end of Southam-
pton's life in good health and good humour, he must give him
store of business to do.' After the king's death, was
encompassed with the ruling powers and resolved in England
at his estate near Southampton, and assisted the
his late master, according both to Clarendon and Knox
with liberal supplies of money. In the letters pressetween Clarendon and the royalists in England were
discovered before the Restoration, there are several proofs
of the secret co-operation. 'I do not undervalue any man,'
Clarendon says, 'as I did in one of these letters, when I say that
Southampton is as wise a man as any the nation has,
most as of honour superior to any temptation. I do not
need to desire you to communicate any things freely.'

('Clarendon State Papers,' iii. 750.)

Immediately upon Charles II.'s return to England the
he stayed for two days at Canterbury on his way
to London, Lord Southampton was made a member
of his privy council; and before the end of the year
was made lord high treasurer. Lord Southampron's
character for judgment and integrity gave a better
administration. Ill health and the natural indis-
 Cheny of his health (as his letters sometimes
speak of) urged him to retire. He was made chancel-
or of the House of Lords, but in the hands of the
secretary, Sir Philip Wi-

wick. In the council he at first strongly advised the
king for a larger fixed revenue than that which
was granted by the convention parliament, and urged
that an act should be passed for
the matter settled; and in the House of Lords he
himself was more disposed to toleration of the Protestant
souls (as he called them) than his friend and colleague Lord Clarendon. He
died at 3 o'clock in the evening of 18 May, 1667, of
consumption, and had long
enjoyed great sufferings in the last years before his
death. Mr. Pepys has the following entry in his diary, dat-
ed two after his death: 'Great talk of the good end
Lord Treasurer made; closing his own eyes, and seeing
dawn, and peace, and liberty, and freedom in the
world: and is said to die with
the cleanest hands that ever any lord treasurer did.'

('Diary,' iii. 222.)

Bishop Burnet has drawn in the following sketch of a
minister, whose innocence in an age of compo-
the chief title to be remembered. 'He was a man of
virtue and of very good parts. He had a lively appre-
sition and a good judgment. He had merited much by
constancy and adherence to the king's interest during
his personal danger, and the charge of his large annual
munificent and extensive gifts only one in the year during his
exile; for he had a great estate, and only
his daughters to inherit it. He was lord treasurer, but
he was a man of the greatest secrecy about business, and
grew very uneasy, and kept himself a
of the way that was consistent with his high
position. He was a man of
spiritual gifts and religious
taste, and his name was long remembered. He was the
child of a man of a great name, and an allow-
c for a table; but he gave, or rather sold, all the sitting
places, and made great profits out of the estate of
crown; but now, that estate being gone, he left
Southampton dissembling to sell places, and began to
be contented, and the lord treasurer to have 8000 a
year, and the king to name all the salaried officers
continued to be so all his time; but that since the
death of lord treasurer has both the 8000l. and a main house
near Richmond.'

('History of His Own Tie,' Vol. i. 175 ed. 1833.)

Lord Southampton was married three times: first, RACHEL, daughter of Daniel, baron de Roffigny, a
to the daughter of Henry, who was created William, viscount Gainsborough, 6th Viscount Pelham and
Francis, lord Dunsmore, afterwards earl of Chichester.
thirdly, to Frances, daughter of William, duke of Squat-
set, and widow of Richard, viscount Moineux.

('Extinct Peerage,' iii. 671.)
WRIST. [Articulation; skeleton.]

WRIT, a law term, which, in its proper and more extensive signification, implies a writing under the king's seal, whereby he confers some right or privilege, or commands some act to be done. Writs are either patent (open, commonly called letters patent, litorer patentes) which are not sealed up but have the great seal attached to them; or close (littera close), which are, or are supposed to be, no more than little letters written to the party: they are subdivided into the following classes and subdivisions:—

1. The writs issued to the plaintiff are either to have the effect of an ordinary suit, or to suspend, prevent, or restrain the defendant from doing anything; and the former are again subdivided into the following classes:

(a) The writs of remedy, which are used to give redress for a wrong done to a person, or to the estate, of the plaintiff; such as damages for an injury done to the person or estate of the plaintiff, or to prevent the defendant from doing anything which would be prejudicial to the plaintiff.

(b) The writs of mandate, which are used to compel the defendant to do some act, such as the delivery of property, or the performance of some duty, or the payment of money. These are subdivided into several classes:

(i) The writs of mandate, which are used to compel the defendant to do some act, such as the delivery of property, or the performance of some duty, or the payment of money.

(ii) The writs of prohibition, which are used to prevent the defendant from doing an act, such as the performance of a duty, or the giving of a certificate, or the payment of money.

(c) The writs of certiorari, which are used to责令 the defendant to render an account of his acts, or to give an answer to a question, or to render a return of a document, or to give a certificate.

2. The writs issued to the defendant are either to have the effect of an ordinary suit, or to restrain the plaintiff from doing anything; and the former are again subdivided into the following classes:

(a) The writs of discovery, which are used to compel the plaintiff to produce certain documents, or to give an answer to a question, or to render a return of a document.

(b) The writs of replevin, which are used to restrain the plaintiff from doing anything, such as the delivery of property, or the payment of money.

3. The writs issued to the court are either to have the effect of an ordinary suit, or to restrain the defendant from doing anything; and the former are again subdivided into the following classes:

(a) The writs of mandamus, which are used to compel the court to do some act, such as the delivery of property, or the performance of some duty, or the payment of money.

(b) The writs of scopo, which are used to restrain the court from doing any act, such as the performance of a duty, or the giving of a certificate, or the payment of money.

(c) The writs of admissio, which are used to admit the plaintiff to the court, or to give him a certificate, or to render a return of a document.

(d) The writs of digestion, which are used to direct the court to render an account of its acts, or to give an answer to a question, or to render a return of a document.

WRIT OF TRIAL. All trials of causes in the superior courts took place formerly either at bar before the whole court, or at nisi prius before one of the judges of the court, or at nisi prius in the counties, before the deputy or the judge, as the case might require. But now, by the 3 and 4 W. IV., c. 42, s. 17, in any action depending in any of the superior courts for any debt or demand in which the sum sought to be recovered is £10 or less, the cause may, by the party desiring it, be directed to be tried by the sheriff of the county where the action is brought, or by some other officer, the same as if it were a petit jo, and the judgment of the sheriff, or of the judge, as the case may be, shall be final. But in all other cases, the superior court may, upon the application of the plaintiff, order the cause to be tried by the court, or by a judge, if satisfied that the trial will not involve any difficult question of law or fact, or that the cause is not of the kind or subject matter to which this mode of trial is applicable. The statute applies only to actions for a debt or demand in a debt or demand of £10 or less, and only to those cases where the action is brought in the county, or in the county where the defendant resides, or in the county where the cause of action arose. The sheriff, usually take place before his under sheriff or other his deputy; and they are conducted in the same manner as at nisi prius; and the court will take place at the same term of court, unless the judge of the court directs otherwise. But if the trial has been before one of the superior judges; but a new trial will not be granted upon the ground that the verdict is against the evidence, where the amount of such verdict is less than £10, unless such verdict be manifestly perverse.

WRITER, in Scotland, is a term of nearly the same meaning as attorney in England, and is generally applied to all legal practitioners who do not belong to the bar, although it has of late become customary to substitute for it the term solicitor. As special exceptions, the body of Mandamus, and Quo Warranto, and Prohibition, are the specimens of the privileges of conducting cases before the Court of Session, the Court of Justiciary, &c., are called solicitors of supreme courts (abbreviated S. C.). The practical point is, that the court of Appeal in Scotland, as the highest court of appeal in the country, is generally a society of writers privileged to practice in the sheriff court and in all the local courts, and to conduct their own by-laws, and to regulate the terms of admission for their conduct to the local judges before whom they practice, and as bodies they are, on the one hand, protected from the infringement of their privileges by unlicensed persons, and, on the other, liable to discipline for misconduct, and for the use of admission to their practice.

WRITER TO THE SIGNET, abbreviated W. S., is the designation of the members of the most numerous and
WRAY.

WRY. 

In literature, the name of a large number of species, but the genus

WRAYNECK. Xancus torquilla. Linn.

General Character.—Bill short, straight, deeply cleft. Mantle bluish, naked, partly closed by a membrane. Tongue long, wiry, and serrated. Wings moderate, second quill longest. Tail feathers forked. Feet with two anterior toes joined together, and two behind unconnected.

Description of Xancus torquilla.—Male.—Ground-color light, with the image of the throat and neck, a large brown streak extending from the occiput to behind the ear. The upper parts are strongly shaded with brown, the back and tail are of this color. The sides of the body have a more decided, the breast and front of the neck pale rusty, with transverse black lines; bill and feet olive-brown, pale hazed or yellow-brown. Total length seven inches.

Female with the tints less vivid, the band on the tail of the male, and on the back not so long as in the male.

Varieties.—Pure white. Yellowish white. Geographical Distribution.—Denmark, Sweden, Norway, Germany, where it is rare; France, Spain, and Italy (summer); England, Wales, and S. France. It is sometimes met with in the last and in the north of the breed. Not recorded in Ireland. Kamtschatka, Illustra, Himalaya Mountains. Winter residences, N. America and warm parts of Western Asia.

This is the true Juncus, the Greeks, Ando, was well pleased with its long tongue, its power of spreading and retracting it, and the muttering motion which it can impart to its neck without the rest of the body. (Hist. Anim, ii, 12.) It has always made familiar to most of our literary readers the familiar name Theocritus Pharamon. It is also the Juncus of the antient Italians. (Pliny, &c.) The Juncus is the boreal of the French, and the Terecito, Terec-o, Terec-t, and Terec- of the Spanish according to Belon; Terecillo, Collaitata, Sierb, petero, Vertilla, and Formicula of the Italian; Gryph of the Swedes; Bende-Huls of Brunswick, Nationus of the Germans, Hunchet, Brunche, and Corpset of the Frenchmen. The Long-Tongue, Emmet-hunter, Snake-Bird, Cuckoo, Cuckoo Maid, Cuckoo's Maid, and Cuckoo Fowl (now Gloucestershire) of the modern British; Goyagi, Gieddori, of the antient British; Aviosi of the Istrians. The neck may be looked for; and from its adventurist at about the same time, some of the modern British it may be seen by the name of the antient British appellations; for gog, must have originated, for in other respects it is not the same as the true Juncus.

The general habits of the species are well described by Mr. Yarrell in his 'British Birds,' He remarks that when found in its retreat, in the hole of a tree, or in a towel, it makes a loud hissing, and stretches out its neck towards each shoulder with grotesque terrors (whence its name Snake-Bird), becomes as male of terror to a timid intruder, when the bird, taking advantage of a moment of indecision, dashes with the speed of lightning from a situation whence escape seems possible.

Caterpillars and a variety of insects form the food of Wyrebeck, and it is a great devourer of ants and their nests. Eldestberry has been mentioned as being a part of its food. Mr. Yarrell states, that the species, which is a large and vigorous one, is found on berried branches of the berry, and the exercise of the muscles attached to it, is able to extend the tongue with such rapidity, that the bird, when the tongue is horny and hard; a large and long gosu-nerated at the under edge of the lower jaw on each side which secretes a glutinous mucus, and transfers the nest from the side of the mouth, where the glutinous mucus the end of the tongue is always covered, was the especial purpose of conveying food into the mouth. The woodcock. So unerring is the aim with which the bird darts out, and so certain is the effect of the stroke, that the bird never fails in obtaining its prey at every attempt. So rapid also is the action of the tongue, in thus conveying food into its mouth, that the observer scarcely has time to make a distinct note of it.
Colonel Montagu says, 'We were enabled to examine the manners of this bird minutely, by taking a female from her nest, and confining her in a cage for some days. A quantity of mould with emmets and their eggs was given it, and it was curious to observe the tongue darted forward and retracted with such velocity, and with such unerring aim, that it never returned without an ant or an egg adhering to it, not transfixed by the horny point, as some have imagined, but retained by a peculiar tenacious moisture, by nature provided for that purpose. While it is feeding, the body is motionless, the head only is turned to every side, and the motion of the tongue is so rapid that an ant’s egg, which is of a light colour and more conspicuous than the tongue, has somewhat the appearance of moving upwards towards the mouth by attraction, as a needle flies to a magnet. The bill is rarely used except to remove the mould in order to get more readily at these insects; where the earth is hollow, the tongue is thrust into all the cavities to raise the ants; for this purpose the horny appendage is used as a guide to the tongue. We have seen the Green Woodpecker take its food in a similar manner.’

The nest is little or null, the smooth, shining, white eggs—from six to ten in number—being generally deposited in the hole of a tree on the decayed wood. The birds are remarkable for local attachment, as the following anecdote, related by Mr. Salmon, will prove:—I wished, writes that gentleman, last spring to obtain the eggs of a wryneck to place in my cabinet, and accordingly watched a Kolb pair that had resorted to a garden for the purpose of incubation; I soon ascertained that they had elected a hole in an old decayed apple-tree for that purpose, the entrance to which was so small as not to admit my hand. The tree being hollow and decayed at the bottom near the ground, I was enabled to reach the nest by putting my arm upwards, and I found, on withdrawing the nest, that the underneath part of it was composed of moss, hair, &c., having every appearance of being formed of the parts of the preceding summer, which I suspect was the case: the upper part was made of dried roots. The nest did not contain any eggs, and I removed it by thrusting it up in the inside of the tree. On passing by the same tree a week afterwards, my attention was arrested by observing two birds leaving the hole, upon which I gently withdrew the nest, and was much gratified at finding it contained six very beautiful glossy eggs, the shells of which were perfectly white, and so transparent that the yolks shone through, giving them a delicate pink colour, but which was lost in the blowing. I replaced the nest and visited it during the ensuing week, and was induced, out of curiosity, to examine it again, when, to my astonishment, I found five birds had not deserted the hole, she having laid six eggs, but only that hid her first, which had adhered to her hair that had not deserted the nest, I kept them, as I was only able to replace the nest by again thrusting it up in the inside of the tree as before, which I did. I again visited the spot in the following week, and saw that they had still perinastically adhered to their female, had hatched out, and that four eggs more had repeated the experiment, but not having an opportunity of visiting the tree until ten days afterwards, I thought at the time that the nest was abandoned, and was not undeceived until I had again withdrawn the nest, having taken the precaution of endeavouring to frighten the old bird off should it be on the nest, which I found was the case, she suffering me to pull the nest to the bottom of the tree before she attempted to escape; there were seven eggs, which are not uncommon. It appears upon William of Malmesbury, who calls Wolstan a cantor of the church of Winchester, says that he also composed an exceedingly useful work on the Harmony of Tones; but that is no longer extant. Bale says he wrote a Life of King Ethelwulf, which is probably a mistake.

The Wryneck.

WULSTAN, otherwise WULFSTAN, or sometimes WOLSTAN. Of these names, which appear to be only variations of the one of the other, there are three Anglo-Saxon ecclesiastics and writers of more or less celebrity.

WULSTAN, a monk of Winchester, of the tenth century, to whom all the three forms of the name are given, is the author of a Latin prose Life of Bishop Ethelwold, whose disciple he had been, and also of a work in Latin hexameter verse (with a prologue in elegiacs) on the miracles of St. Swithin. The former, which is a very poor composition, is printed in the 5th sacram of Mabillon's Acta Sanctorum Ordinis S. Benedicti, fol. Paris, 1806, pp. 606-624. Of the latter only the introduction has been printed (in the same volume, pp. 623-624); but the whole is preserved in several manuscript copies. The verse, though not of much merit, has the reputation of being the best Latin poetry known to have been produced in England in that age. It appears upon William of Malmesbury, who calls Wolstan a cantor of the church of Winchester, says that he also composed an exceedingly useful work on the Harmony of Tones; but that is no longer extant. Bale says he wrote a Life of King Ethelwulf, which is probably a mistake.

WOLSTAN, who was not a monk, became archbishop of York in 1008, holding along with that dignity the bishopric of Worcester, as had also been done by his two immediate predecessors, and died in 1023. There is extant in MS. a letter addressed by him in Anglo-Saxon to the people of his province; and he is supposed by Walney, on probable grounds, to be the Lupa Epicopou to whom are attributed certain sermons or homilies of this age written in the same language. The most remarkable of these is printed, with a Latin translation and notes by William Elstob, in the Dissertatio Epistolarius, contained in Vol. XXVII. 4 G
in the third volume of Hickes's 'Thesaurus,' fol. 1705, pp. 99-100; and there is also a separate edition of the same volume, the fol. 1705, in which the two are contained, the latter is formed, in fol. 1705, of two pastoral letters in Anglo-Saxon written in the name of Wulfstan, by one (which one is matter of dispute) of the two Alfries, with both of whom he appears to have had a personal friendship; the other is said to have been composed in Latin, and then, at Wulfstan's desire, to have been translated into Saxon, that they might be more generally useful.

3. WULSTAN. Bishop of Worcester, is stated by his biographer, William of Malmesbury, to have been born at Tewceton in Warwickshire, to a fair estate; the name of his father was Ethelstan, that of his mother Wulfgiva. From the age he is stated to have attained at his death, his birth must have happened in 1007 or 1008. He began his episcopate in the midst of the persecution of Evesham, but was afterwards removed to the more distinguished seminary of Peterborough. Having at the usual age been ordained a prebendary, he soon after became a monk at Worcester, and gradually rose to be at last prior of the monastery there. In 1062 he became bishop of Worcester on the nomination of Aldred, who, having been two years before removed from that see to the archbishopric of York, had attempted at first, as had for some time been customary, to retain both sees, but was at last, in 1062, removed to Worcester in consideration of only being permitted to name his successor. He chose Wulstan, it is said, conceiving that his mild temper and simple character would prevent him from offering any resistance to his patron's appointment. The estates and benefices upon the see of the see. But this turned out to be a great mistake. Wulstan proved a very danger of a bishop, and, especially after the coming over of the Norman conqueror, to whom he very naturally proved such a valuable ally, that he not only set Aldred at complete defiance, but even compelled his successor, Archbishops Thomas, to make restitution to the see of Worcester of sundry lands or pecuniary dues of which it had been deposed by his predecessor. He also successfully resisted the claim of the archbishopric of York to a jurisdiction over the diocese of Worcester, and got that bishopric declared by the king to be in the province of Canterbury. Wulstan continued in the same favour with Rufus which he had enjoyed with his father; and in the beginning of the new king's reign, old as he was, he proved very serviceable in putting down an insurrection of the adherents of Duke Robert of Normandy, defending his city of Worcester against an army of the rebels led by Roger de Montgomeroy. Wulstan almost rebuilt the cathedral of Worcester from the foundation; and he died in that city, at the age of eighty-seven, on the 19th of January, 1069. Wulstan is not known to have written anything either in Saxon or Latin, but his discourses are said to have been a ready and effective speaker in the former language; but in the work entitled 'Antient History, English and French, exemplified in a regular dissertation of the Saxon Chronicle,' 12mo. Lond. 1830, an attempt is made to show that he was the author of the portion of that venerable record extending from A.D. 1034 to the end of the reign of William the Conqueror. There are two accounts of Wulstan by William of Malmesbury: one in his work 'De Gestis Pontificum,' the other a separate Life, in three books, which is published in the second volume of Wharton's 'Anglia Sacra.'

(Wright's 'Biographia Britannica,' Literarum, vol. 1.)

WURMER, DAGOBERT-SIGISMUND, COUNT OF, a distinguished Austrian general, was born on the 22nd of September, 1724, in Alsace—the territory which now constitutes the French departments of the Upper and Lower Rhine. He commenced his military career in the French service, and having distinguished himself by his conduct in the campaigns of 1746-7, was raised to the rank of captain in the cavalry. His father having resolved to settle in the Austrian states, and become an Austrian subject in 1750, Dagobert resigned his commission and accompanied him. Such emigrations from the French Rhine provinces were at that time far from common: the Alsatians, though French subjects, were then unmixed Germans; in fact the century which has since almost elapsed has only stripped their character of its German nationality, without giving them a French one.

Douglas—Sigismund Wurmser was well received at Vienna. Maria Theresa conferred upon him the officer's coronet of the Austrian, and the Order of the Black and White. He valued less a troop of hussars, which he continued to command throughout the whole of the Thirty Years War. After the battle of Prague he was made Major-General, after that of Lissa, Colonel; after that of Isselburg, Lieutenant General; and after that of Leignitz he obtained the cross of the Order of Maria Theresa. His kind disposition and generosity rendered him the idol of both the officers and men under his command. There is a story told of him illustrative of these features of his character. Having, after the battle of Gotzitz, that a brave but poor lieutenant of cavalry had lost his horse in the action, Wurmser set him one of the best in his stables, with a message to the effect that, having sworn this horse should belong to the bravest men in the army, he begged his acceptance of it.

In 1773 Wurmser became proprietary colonel of a regiment of hussars which subsequently bore his name; and, when the war broke out again in 1778, he was raised to the rank of Lieutenant-General. At the head of a body of 12,000 men, he broke into the territory of Glatz, and on the 18th of January, 1779, surprised the Prussians at Kubelschwerd and defeated them, taking 12,000 prisoners.

The period of Wurmser's career which obtained for him a European reputation commenced in 1780. In January of that year he was sent to the province of Galicia, and the collar of commander of the order of Maria Theresa was the reward of his exploits during that short campaign.

In 1787 he was appointed general-commandant of the province of Galicia, and although the inhabitants were extremely averse to the Austrian yoke, he contrived to make himself a personal favourite. The emperor Joseph bestowed on him the appointment of Feldscheidermeister of that province, with the character of general, and Wurmser was not employed in the war against the Turks in 1789.

to him the secret of the correspondence between the Prince of Condé and Pichegru. That Austria should have made no effort to turn that negotiation to account was not surprising. In the sincerity of the republican general that power could not have a little confidence, and in the judgment of the Prince of Condé still less. Besides the anxiety of Condé and Pichegru to keep their intercourses a secret from the Austrian government was of itself suspicious. The conspiracy was allowed by Wurmser, the archduke Charles, to be too well known east and west, and it led to nothing but its very natural termination in the ruin of the general who had intrigued with the enemies of his country to subvert the government from which he held his commission. Wurmser, defeated in the battle of the Necker, on the 28th and 29th of October, 1791, entered Mannheim; the citadel surrendered after a bombardment which lasted a few days.

On the 1st of January, 1796, Wurmser received the grand cross of the order of Maria Theresia. His part in the campaign did not recommend him that year till the month of May. On the 15th of June Wurmser gave way before the attack of Moreau and abandoned Frankenthal. The Austrian cabinet, which had relinquished the idea of assuming the offensive in Alsace and on the Rhine, ordered him to move thirty thousand of the best troops in the army under his command without delay upon the north of Italy. An opponent full of the impetuosity of youth and the resources of genius awaited the exasperated general.

On the 15th of July Wurmser advanced towards Mantua. He drove in the French outposts on the Lago di Garda; but Bonaparte, having abruptly broken up the siege of Mantua to precipitate himself on his adversary, met and beat him at Lonato, 1796, 640 feet high, and on the 5th, then at Roveredo, and on the 8th at the gorges of the Brenta. The Austrian general, far from despairing, made an attempt upon Verona; but, repulsed by General Kell- maine, he retreated along the Adige with 6000 foot and 1500 cavalry. He crossed the Brenta, 3640 feet high, and two French divisions detached to watch his motions, threw himself into Mantua. This place was vigorously and skillfully defended by Wurmser; but the defeat of the troops under Alvinczy, want of provisions, and sickness among the garrison, forced him to surrender on the 24th of February, 1797, in the judgment of the best observers, with that chivalrous spirit which marked his early career, left the veteran entire personal liberty, saying that he respected his years, and did not wish to make him the victim of the intrigues who would doubtless avail themselves of his absence to undermine him at Vienna. Wurmser repaid the generosity of the French general in kind: having detected a plot to poison Bonaparte, he put him under his guard.

On Wurmser's return to Vienna, the emperor appointed him vice-archduke. He waged with beauty and patience the war of the confederates. He did not however survive to take possession of his government, dying at Vienna in the month of June, 1797. He was never married: his estates and honours were inherited by a nephew.

The ‘Reise de St.-Hélie’ erroneously attributes to Wurmser the rank of field-marshal, which he never attained. His military skill is unquestionable, notwithstanding his career during the revolutionary war was an almost unbroken series of reverses. It was his fate to command at a time when the revolutionary fervour for a time broke through all the calculations of tacticians. Time has shown that this preternatural stimulus must wear itself out, and organised discipline reassert its ascendancy. Wurmser was one of the first to produce a reaction in Austria Europe during the period of the army's reverses. Even defeat did not for a moment obscure his personal merit; and to the hopeful and persevering turn of mind of Wurmser, the archduke Charles, Brucker, and a few others, it was in great part due to the variety of occupation which survived to assert their due influence when the maniacal revolutionary period had passed over. Personally Wurmser was brave, frank, and benevolent, with a strong devotional turn. To his honour let it suffice to its justice that when, as a Roman Catholic, he unceasingly asserted the right of Protestant soldiers in the Austrian army to perfect religious freedom.

The outline of incidents of this sketch of Wurmser is taken from the ‘Reise de St.-Hélie’, the ‘Biographie Universelle’ and its supplement, checked by reference to the writings of Napoleon, Jomini, the archduke Charles, &c.
**Agriculture.**—The whole of the public and private property contains—

- Arable | 2,440,000 | 1,798,314 |
- Meadows | 738,000 |
- Gardens | 148,000 |
- Vineyards | 84,777 |
- Wine | 2,500,000 |

**Württemberg Acres.**

Württemberg is one of the most fruitful countries of Germany, and agriculture is on the whole carried on upon a good system; the want of sufficient manure is however a great drawback. Great improvements have been made during the present reign, by the encouragement given by the government, and particularly by the encouragement given by the king. The very rigorous laws for the protection of the game have caused the wild-boars, deer, and hares in particular, to multiply to such a degree as to be most injurious to the farmers. But the king's system and the measures of the flourishing prince have completely put an end to this nuisance; an ordinance, issued in 1817, commands the wild-boars to be exterminated in the forests, and to be confined to the enclosed parks; the deer to be diminished as little as possible by the encouragement given by the government.

The forests yield a great variety of fish, which are a source of considerable profit. In some parts of the kingdom bees are kept; there are in all about 70,000 hives. Lives between this years silk-worms have been introduced, with every prospect of success. Leek is bred in ponds appropriated to that purpose, and edible snails in separate reservoirs.

**Manufactures.**—There are manufactures of almost every description, and though not on so extensive a scale as in some other parts of Germany, they are of considerable importance, and extraordinary progress has been made since the conclusion of the general peace in 1815. The principal are the production of the finest sorts, to which the new instituted Pomological Society is expected to contribute.

The metals and minerals are copper, lead, zinc, iron (at least 5000 tons annually), malleable lead, millstones, freestone, gypsum, quartz, garnet, tourmaline, amethyst, chryso-
olites, rock-crystal, agate, chalcedony, carnelian, opal, jasper, porcelain earth, petteland, fuller's earth, chalk, marl, coal, but not in mineral quantity, and metals. The king's system and the measures of the flourishing prince have completely put an end to this nuisance; an ordinance, issued in 1817, commands the wild-boars to be exterminated in the forests, and to be confined to the enclosed parks; the deer to be diminished as little as possible by the encouragement given by the government.

The principal are the production of the finest sorts, to which the new instituted Pomological Society is expected to contribute. The metals and minerals are copper, lead, zinc, iron (at least 5000 tons annually), malleable lead, millstones, freestone, gypsum, quartz, garnet, tourmaline, amethyst, chryso-
olites, rock-crystal, agate, chalcedony, carnelian, opal, jasper, porcelain earth, petteland, fuller's earth, chalk, marl, coal, but not in mineral quantity, and metals. There are manufactures of almost every description, and though not on so extensive a scale as in some other parts of Germany, they are of considerable importance, and extraordinary progress has been made since the conclusion of the general peace in 1815. The principal are the production of the finest sorts, to which the new instituted Pomological Society is expected to contribute.

**Commerces.**—Though Württemberg cannot be properly called a commercial country, it has a very considerable and profitable trade. The exports consist of the natural productions and manufactures, that is, bread, and all kinds of eatable food, as pears, apples, peaches, plums, and other fruits, wine, and other produce of the land, and the export of the produce of the mines, which include the following minerals: iron, copper, zinc, lead, tin, antimony, silver, and lead. The principal are the production of the finest sorts, to which the new instituted Pomological Society is expected to contribute.

**Population; Religion.**—With the exception of about 12,000 Jews and a few families of Waldenses, and some foreigners, the population is entirely German, partly...
Suabian, partly Franconian, according as they originally belonged to those two circles, the dialect of which they retain. *They are,* says Fischer, "a robust good-looking race of men, but of late years the health of the women in the middle and higher classes has been less vigorous than formerly, and especially in the Roththal and Kochertal, where swollen necks and goitres are extremely common. The main feature of the character of the people is goodness-nature, rather phlegmatic than lively; they are honest, fond of their country, and have been known to suffer severe taxes, the injudicious police measures, and the licentious spirit of the times have had a pernicious influence on their character and morals. To these circumstances we may ascribe the very extraordinary number of robberies and other great crimes; and the turn of the public course of life may be found perhaps in the too great leniency which is shown towards the guilty. With respect to religion the majority are Protestants: the proportion in 1834 was as follows:

<table>
<thead>
<tr>
<th>Sect</th>
<th>Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>Protestants</td>
<td>1,124,021</td>
</tr>
<tr>
<td>Roman Catholics</td>
<td>485,200</td>
</tr>
<tr>
<td>Jews</td>
<td>22,206</td>
</tr>
<tr>
<td>Not specified</td>
<td>177</td>
</tr>
<tr>
<td>Total</td>
<td>1,634,545</td>
</tr>
</tbody>
</table>

The annual increase by the excess of births is above 9,000; but as the loss by emigration much exceeds what is added by immigration, the annual increase is not above 7,000.
